Now from the observations of La Perouse and Krufenstern, the westerly variation ceased, and the curve of no variation terminated in about 52° N. lat., and 153° E. long., for the variation north-east of this point assumes another character; and 18° farther north, and 52° to the east, captain Cook found near 56° of easterly variation.

It appears also, from a comparison of observations made in Perisia and the frontiers of China by Schubert, with those of Peroufe, Krufenstern, and others, made on board his majesty's ship Sybille by Mr. Bain, that a curve of no variation again takes its rise in about 52° N. lat., and 143° E. long., and terminates a little east from Spitzbergen, extending in a direction nearly east by south, and west by north, through 67° 80 miles of longitude.

Biot, in speaking of this subject, says, "that a curve of no variation seems to take its rise in the great Southern ocean, passing through the western part of New Holland, traversing the Indian ocean, enters the continent of Asia at Cape Comorin, and thence passes through Perisia and West Siberia, and proceeds towards Lapland. But what is more remarkable, that line divides itself into two in the great Asian archipelago, and gives rise to another branch, which, pointing directly from the south to the north, passes that archipelago, traverses China, and is again found in Eastern Siberia. The existence of this branch, and its separation from the former, are clearly indicated by the observations made in the Chinese seas; but I am able to offer a still farther confirmation of it, by the observations made in Russia and the frontiers of China, by the celebrated astronomer Schubert, who has been kind enough to communicate them to me," which latter are the observations spoken of above.

We have seen that a curve of no variation, extending from 60° of south latitude to 52° of north latitude, in about 143° east longitude, but taking a small bend to the westward, is interfered by the meridian of Ambayona; and by comparing with each other different observations made by Mr. Wales, in his voyage with captain Cook, and those of Vancouver in 1791, and others made by sir Home Popham, and by Humboldt, it appears, that from the westerly part of the curve of no variation, found in about 130° east of the meridian of Greenwich, where the westerly changes to an easterly variation, to the meridian where the easterly variation

Vol. XXXVI.
VARIATION.

tion was found to terminate by captain Cook, S. lat. 58° 27', W. long. 13° 10', the distance east and west will be 210° 50'.

To the meridian of Pororou, S. lat. 20° 39', W. long. 28° 28', the distance is 201° 22'.

To the meridian of Vancouver, S. lat. 35° 40', W. long. 28°, the distance is 202°.

To the meridian of sir H. Poplham, S. lat. 30°, W. long. 26°, the distance is 204°.

To the meridian of Humboldt, N. lat. 15° 40', W. long. 79°, the distance (taking the mean) is 171°.

And if the curve of no variation extends to N. lat. 37° 27', W. long. 70° 40', the eaft-ward variation in that parallel will only measure 158° 16'.

These different distances point out, under different parallels of latitude, the direction in which the curve of no variation at present affumes; and we may perhaps conclude, that the variation of the magnetic needle is caused by two different and distinct systems of magnetic forces; the one producing a westerly variation in the northern hemisphere, over the space of 200° 44', and in the southern hemisphere, in the same parallel of latitude, of 14° 10'; and the other an eaft-ward variation in the northern hemisphere, over a space of 159° 10', and on the southerm, of 216° 50'.

From these facts it would seem, that the north end of the curve, which passed Cape Aguilas in 1600 north-eaftward, was in 1804, found to extend from S. lat. 60°, W. long. 13° 13', to N. lat. 37° 27', W. long. 70° 40', intersecting the 12th degree of north latitude, and the 218th, 30th, and 335th of south latitude; whence the mean rate of its motion is found to be 265 miles annually: but it is extremely probable, that the south end of this curve has during the same period remained stationary; and this difference in the direction of the two extremes of the curve in the southern hemisphere, may perhaps point out to us the reason why the quantity of variation should have continued the same off Cape Horn during 133 years, while at the Cape of Good Hope, Paris, and London, it should have increased 25° or 27° in the same period.

The curve of no variation which passed through London eaftward, about the same time the curve in the southern hemisphere passed the meridian of Greenwich eaftward, appears to have been loft among the smaller magnetic powers at present found in the continent of Europe and Asia.

The view which we have given of this perplexing subject, deduced from actual observation, renders it obvious that all attempts, by theory, to fix on charts the exact positions of the curves of no variation, or of lines of given variation, must prove, as they have always hitherto done, entirely abortive. There are indeed places in the world, such as Spitzbergen, Cape Horn, Chili, and Mexico, the great Aflan archipelago, the coast of Coromandel, Peru, Brazil, &c., where the curve of variation, and the variation itself, has not undergone any perceptible change since first observed; but we have good reasons to believe, that at all the above-mentioned places the variations are regulated by incidental magnetic attractions, which are lost or merged in the two great powers already deferred, at a little distance from their respective spheres. In all other places of the globe, it is continually undergoing a regular and progressive change; but it is impossible accurately to determine when this change may cease, or to foretell what quantity our present westerly variation may attain, though there is some reason to believe it has very nearly or entirely arrived at its maximum.

At present, we have spoken only of those great and in former measure continued changes in the variation which takes place, and become very obvious after a long period; but there are others of a more minute quantity, and of daily, and we might add of hourly occurrence, to which it will be proper to refer in the present article.

Mr. George Graham made several observations of this kind in the years 1722 and 1723, professing himself altogether ignorant of the cause of the variation which he observed. Phil. Trans. Nof. 383, or Abr. vol. vii. p. 290, &c.

About the year 1750, Mr. Wargentin, secretary of the Royal Academy of Sciences in Sweden, took notice both of the regular diurnal variation of the needle, and also of its being disturbed at the time of the auroa borealis, as record'd in the Phil. Trans. vol. xlvi. p. 126, &c.

About the year 1756, Mr. Canton commenced a series of observations, amounting to nearly 4000, with an excellent variation-compas, of about nine inches diameter. The number of days on which these observations were made was 603, and the diurnal variation on 574 of them was regular; i.e. the absolute variation of the needle eastward was increasing from about eight or nine o'clock in the morning till about one or two in the afternoon, when the needle became stationary for some time; after that, the absolute variation eastward was decreasing, and the needle came back again to its former situation, or near it, in the night, or by the next morning. The diurnal variation is irregular when the needle moves slowly eastward in the latter part of the morning, or westward in the latter part of the afternoon; also when it moves much either way after night, or suddenly both ways in a short time. These irregularities seldom happen more than once or twice in a month, and are always accompanied, as far as Mr. Canton observed, with an aurora borealis.

Mr. Canton lays down and evinces by experiment the following principle, viz. that the attractive power of the magnet (whether natural or artificial) will decrease while the magnet is heating, and increase while it is cooling. He then proceeds to account for both the regular and irregular variation. It is evident, he says, that the magnetic parts of the earth in the north on the east side, and the magnetic parts of the earth in the north on the west side of the magnetic meridian, equally attract the north end of the needle. If then the eastern magnetic parts are heated faster by the sun in the morning than the western, the needle will move eastward, and the absolute variation will increase; when the attracting parts of the earth on each side of the magnetic meridian have the heat increasing equally, the needle will be stationary, and the absolute variation will then be greatest; but when the western magnetic parts are either heating faster, or cooling faster than the eastern, the needle will move eastward, or the absolute variation will decrease; and when the eastern and western magnetic parts are cooling equally fast, the needle will again be stationary, and the absolute variation will then be least.

By this theory, the diurnal variation in the summer ought to exceed that in winter; and accordingly it is found by observation, that the diurnal variation in the months of June and July is almost double that of December and January.

The irregular diurnal variation must arise from some other cause than that of heat communicated by the sun; and here Mr. Canton had recourse to subterranean heat, which is generated without any regularity as to time, and which will, when it happens in the north, affect the attractive power of the magnetic parts of the earth on the north end of the needle. That the air nearest the earth will be most warmed by the heat of it, is obvious; and this has been frequently taken notice of in the morning, before day, by means of thermometers at different distances from the ground. Phil. Trans. vol. xlvi. p. 526.

Mr. Canton has annexed to his paper on this subject a complete
complete year's observation; from which it appears that the
durnal variation increases from January to June, and
decreases from June to December. Phil. Tran. vol. li. p. 398, &c.

It has also been observed, that different needles, especially
if touched with different load-fores, will differ a few min-
utes in their variation. See Poleni Epift. Phil. Tran. N° 421.

We shall here subjoin a method practised by M. Du Hamel,
who was one of those who attempted, and succeeded in the
preparation of artificial magnets, for enlarging the scale of
the variation. At each extremity of the needle, composed
of two magnetic bars, and which is fourteen inches long, a
slender pointed piece of steel is erected perpendicularly; and
at the distance of fifty-two feet, in the direction of the
needle, he has placed on two pillars, and in a line perpendi-
cular to that direction, a graduated limb six feet long; being
a segment of a supposed circle, described from the centre
on which the needle turns. The observer, placing himself so
as to bring the two pieces of steel at the extremities of the
bar into a line with the eye, observes where that line pro-
longed, or the vital ray, points to the graduated arc. As,
at this distance, each of these degrees measures a foot, the
true direction of the needle is ascertained with the greatest
precision; and left the observer's eyes may not be good
enough to enable him to see distinctly the particular divisions
at that distance, an affistant occasionally moves a certain in-
dex, conformably to his direction. Hift. de l'Acad. Roy.

On the Effét of the local Attraction of the Ship upon the
Variation of the Needle.—We have already had occasion to
notice the necessity of attending to the direction of the ship's
head, in observations made on ship-board relative to the
direction of the compais; and that this may have a very
sensible effect will appear very obvious, when we recollect
the quantity of iron with which a ship of war, in particular,
is generally loaded; and that this is mostly forward, while the
compais is generally aft. The great attraction between the
iron and the needle is generally known; and consequently,
if we could imagine the magnetic power of the earth to
be equal entirely, we should have no difficulty in conceiving
that the attraction of the guns, &c. would incline the needle
to assume a direction coinciding with that of the vessel;
and consequently, when the magnetic meridian and the direc-
tion of the ship are the same, that, when the vessel lies north
and south, both forces acting in the same manner, the po-
tion of the needle will be the same as if no such local
attraction existed. But if the ship's head is put over to the
east or the west, then the local attraction of the ship will in-
cline the needle to the east and west, while the terrestri-
al attraction will draw it towards the north; and it will, there-
fore, assume a direction which corresponds with the re-
Sultant of these two distinct forces: and we may observe,
that the direction of this resultant would furnish, if well ob-
erved, most important data towards determining the inten-
sity of this mysterious power.

Simple and obvious as this idea is, it does not appear to
have been formed till Mr. Wals, the astronomer in captain
Cook's voyages, was struck with certain irregularities,
which he could in no way at first account for, and of which
we have the following account in the Introduction to the
astronomical observations in the Second Voyage.

"In the English Channel, the extremes of the observed
variation were from 19° to 25°; and all the way to the
Cape of Good Hope, I had frequently observed differences
nearly as great, without being able in any way to account
for them; the difference in the situation being by no means
sufficient. These irregularities continued after leaving the
Cape, which at length put me upon examining into the cir-
cumstances under which they were made. In this examina-
tion it soon appeared, that when most of these observations
were made, wherein the greatest variation had happened,
the ship's head was north and easterly; and that when those
where it was the least had been taken, it was south and
westerly. I mentioned this to captain Cook, and some of
the officers, who did not at first seem to think much of it;
but as opportunities happened, some observations were made
under those circumstances, and very much contributed to con-
firm my suspicions; and throughout the whole voyage,
I had good reason to believe that variations observed, with
the ship's head in different positions, and even in different parts
of her, will differ very materially from one another, and
much more will observations made on board different ships,
which I now find fully verified, on comparing those made
on board the Adventure with my own, made about the same

time in the Resolution."

Mr. Wales again recur to this subject, in the course of
his astronomical observations made in Cook's third voyage,
and points out the quantity of the deviation in several cases;
but the true cause of these anomalies does not appear to have
been sufficiently explained by this able astronomer: he merely
lates the irregularities, but offers no explanation of them.
Nor does it appear that they were afterwards particularly noticed by any nav-
igator, till captain Bligh's attention was called to the sub-
ject in the early part of his last voyage. Here that experienced
navigator found such unaccountable differences in the quanti-
ty of variation, deduced from the different observations
he occasionally made, that he determined on instituting an
inquiry into their causes; and, if possible, to ascertain the
laws by which they were regulated.

"Several influences," he observes, "have been mentioned in
the course of this voyage, where the compas shewed a
different variation, on being removed from one part of the
ship to another. Thus, observations on the binnacle gave
29° off the Start, where the true variation was 25°; whilst
others taken from the bow presented the main-mast, 65 miles
lower down the Channel, gave only 24°; and in the
experiments made with five compas, the mean variation
on the binnacle was 4° 37' greater than on the
booms.

"It soon became evident, however, that keeping the
compas to one spot was not alone sufficient to secure ac-
curacy: a change in the direction of the ship's head was also
found to make a difference in the needle; and it was neces-
sary to ascertain the nature and proportional quantity of this
difference, before a remedy could be applied. This inquiry
was attended with many difficulties, and no satisfactory con-
clusion could be drawn, until a greater variety of observa-
tions was collected. It then appeared, that when the
ship's head was on the easter side of the meridians, the dif-
fferences were mostly one way: and when on the west side,
they were the contrary; whence I judged that the iron in the
ship had an attraction on the needle, which drew it forward.
But there was this remarkable distinction: in the northern
hemisphere, it was the north end of the needle which was
attracted; and in the southern hemisphere, it was the south
end. In the influences off the Start, before cited, when the
ship's head was west, the north end of the needle had been
drawn forward, or to the left of the north, nearly 4°, and
the west variation thereby increased to 29°; with the head
at east, it would be drawn to the right of its natural position,
and the variation diminished to about 24°; but at north,
the attraction of the ship was in the same line with the mag-
netic poles of the earth, and would, therefore, produce no

charge.
VARIATION.

The same thing took place at south, for the two attractions were still in the same continued line, though on opposite sides of the compass; and throughout the voyage, I found the variation, taken with the head at north and south, agreed very nearly in themselves, and with the observations themselves near the same place, when such observations were not affected by local attractions."

The following table contains a few of the instances, where the change in the variation was observed by captain Flinders.

Table of Variations observed in a Voyage of Discovery to Terra Australis, in 1801 and 1802, by Captain Flinders, in His Majesty's Ship Investigator.

</table>

After various other observations, and much examination, (for the needle was not always deflected the same quantity, when the position of the ship was the same,) captain Flinders found that the errors had a close connection with the dip. When the north end of the needle had dipped, it was the north point of the compass that had been attracted by the iron of the ship; and as that dip diminished, so had the attraction, until at the magnetic equator; where the dipping-needle stands horizontal, there seemed to have been no attraction; and, upon the whole, it seemed probable that "the error produced at any direction of the ship's head would be to the error at east or west, at the same dip, as the sine of the angle between the ship's head and the magnetic meridian was to the sine of eight points or radius."

After captain Flinders's arrival in England, he made application to the lords commissioners of the Admiralty to have experiments tried on board some of his majesty's ships, that the observations made during his voyage might be verified; and a series of observations was accordingly made on board five different ships at Sheerness and Portsmouth, which fully established the accuracy of his former conclusions.

Should this rule, upon farther trial, be found to answer under all circumstances, we must consider it as a most important acquisition to our present knowledge of navigation; but those who with fully to appreciate all the consequences of this discovery, should consult Bain's treatise on the "Variation of the Compass," to which work we have been much indebted in the composition of this article, and where they will find every information of a practical kind connected with the subject.

Theory of the Variation of the Needle.—Dr. Halley, as we have already stated, was the first who attempted any theory relative to the variation of the compass; and from the observations which he collected, many of which are included in our preceding remarks, he conceived "that the whole globe of the earth is one great magnet, having four magnetic
metrical poles, or points of attraction; near each pole of the
equator two; and that in those parts of the world which lie
nearly adjacent to any one of these magnetic poles, the
needle is governed thereby; the nearest pole being always
predominant over the more remote."

The pole which at present is nearest to us, he conjectures
to lie in or near the meridian of the Land's-End of England,
and not above 70° from the Arctic pole; by this pole the
variations in all Europe and Tartary, and the North sea,
are principally governed; though still with some regard to
the other northern pole, whose situation is in the meridian
taking about the middle of California, and about 15° from
the south pole of the world, to which the needle has chiefly
respect in all North America, and in the two oceans on
either side thereof; from the Azores, westwards, to Japan,
and farther.

The two southern poles, he imagines, are rather farther
distant from the south pole of the world; the one about 16°,
in a meridian 20° to the westward of Magellan's straits, or
95° west from London; this commands the needle in all
South America, in the Pacific sea, and the greatest part of
the Ethiopian ocean. The other seems to have the greatest
power, and the largest domain of all, as it is the most remote
from the pole of the world, being distant from it little
less than 20°, in the meridian which passes through New
Holland, and the island Celebes, about 120° east from
London; this pole is predominant in the south part of
Africa, in Arabia, and the Red sea, in Perla, India, and
its islands, and all over the Indian sea, from the Cape of
Good Hope eastwards, to the middle of the Great South
sea that divides Asia from America.

Such appears to have been the disposition of the magnetic
attraction in the time of Dr. Halley; and from these data
this author draws the following conclusions; viz.
1. Then, it is plain that, as our European north pole is
in the meridian of the Land's-End of England, all places
more easterly than that will have it on the west side of
the meridian; and, consequently, the needle, respectful to it
with its northern point, will have a westerly variation, which
will still be greater as you go to the eastern, till you come to
some meridian of Russia, where it will be the greatest, and
from thence will decrease again. Accordingly, in fact, we
find, that at Brest the variation is but 12°; at London, 45°
in 1683; and at Dantzic, 72° west. Again, to the westward
of the meridian of the Land's-End, the needle ought
to have a more easterly variation, were it not that, by approaching
the American northern pole, (which lies on the west
side of the meridian, and seems to be of greater force than
this other,) the needle is drawn thereby westward, so as
to counterbalance the direction given by the European pole,
and to make a small west variation in the meridian of the
Land's-End itself. Yet, about the ile of Tercera, it is
supposed our nearest pole may so far prevail as to give the
needle a little turn to the easterly, though but for a very little
space; the counterbalance of those two poles admitting no
considerable variation in all the eastern parts of the Atlantic
ocean, nor upon the west coasts of England and Ireland,
France, Spain, and Barbary. But to the westward of the
Azores, the powers of the American pole overcoming that
of the European, the needle has chiefly respect to this, and
turns more and more towards it as we approach it.

Whence it happens, that on the coast of Virginia, New
England, Newfoundland, and in Hudson's straits, the
variation is westward, that is, it decreases as you go from
thence towards Europe; and that it is lefs in Virginia and
New England than in Newfoundland and Hudson's straits.

2. This westerly variation, again, decreases as you pass
over North America; and about the meridian of the middle
of California, the needle again points due north; and from
thence westward to Yedo and Japan, it is supposed the
variation is easterly, and half-deer, not less than 15°; and
that this east variation extends over Japan, Yedo, Tartary,
and part of China, till it meets with the westerly, which is
governed by the European north pole, and which is
the greatest somewhere in Russia.

3. Towards the south pole the effect is much the same,
only that here the south point of the needle is attracted.
Whence it will follow, that the variation on the coast of
Brazil, at the river of Plate, and so on to the straits of
Magellan, should be easterly, if we suppose a magnetic pole
situated about 20° more westerly than the straits of
Magellan. And this easterly variation extends easterly
over the greatest part of the Ethiopian sea, till it be counter-
poised by the virtue of the other southern pole, as it is about
mid-way between the Cape of Good Hope and the isles of
Trind d'Alcunha.

4. From thence eastwards, the African south pole be-
coming prevalent, and the south point of the needle being
attracted thereby, there arises a west variation, very great
in quantity and extent, because of the great distance of this
magnetical pole from the pole of the world. Hence it is,
that in all the Indian sea, as far as Hollandia Nova, and
further, there is constantly a west variation; and that, under
the equator itself, it rises to no less than 11°, where it is
most. And that, about the meridian of the island of Cele-
bes, being likewise that of this pole, this westerly variation
ceases, and an easterly one begins, which reaches to the
middle of the South sea, between Zelandia Nova and Chili,
leaving room for a small west variation, governed by the
American south pole.

5. From the whole it appears, that the direction of the
needle, in the temperate and frigid zones, depends chiefly
upon the counterpoise of the forces of the magnetic poles
of the same nature; as also why, under the same meridian,
the variation should be in one place 20° west, and in an-
other 20° east.

6. In the torrid zone, and particularly under the equi-
nocitial, respect must be had to all four poles, and their
positions must be well considered, otherwise it will not be
easy to determine what the variation shall be, the nearest
pole being always strongest; yet not so as to be counter-
balanced, sometimes, by the united forces of two more
remote. Thus, in falling from St. Helena, by the isle of
Ascension, to the equator, on the north-west course,
the variation is very little easterly, and in that whole tract
is unalterable; because the South American pole, (which is
considerably the nearest in the aforesaid places,) requiring
a great easterly variation, is counterpoised by the contrary
attraction of the North American and the Asiatic south
poles; each of which, finely, is, in these parts, weaker than
the American south pole; and upon the north-west course,
the distance from this latter is very little varied; and as
you recede from the Asiatic south pole, the balance is still
preferred by an access towards the North American pole.
In this case, no notice is taken of the European north pole;
its meridians being a little removed from those of these
places, and of itself requiring the same variations which we
have hitherto found.

After the same manner may the variations in other places,
under and near the equator, be accounted for, upon Dr.
Halley's hypothesis. But in order to account for the
variation of the variation, it was observed, that from many
of the observed phenomena, it seemed to follow that all the magnetic poles have a
motion
VARIATION.

motion westward; but if it be so, it is evident that it is not a variation about the axis of the earth; for then the variations would continue the same in the same parallel of latitude (the longitude only changed), as much as the motion of the magnetic poles; but the contrary is found by experience; for there is no where, in the latitude of $51^\circ$ north, between England and America, a variation of $11^\circ$ east, at this time; as it was once here at London. Wherefore it seems, that our European pole is become nearer the Arctic pole than it was heretofore; or else, that it has lost part of its virtue.

But whether these magnetic poles move altogether with one motion, or with several; whether equally, or unequally; whether circular, or libratory; if circular, about what centre; if libratory, after what manner; are things yet unknown.

This theory seems yet somewhat obscure and defective; to suppute four poles in one magnetic globe, in order to account for the variation, is a little unnatural; but to conceive these poles to move, and that by such laws as to solve the variation of the variation, is still more extraordinary. In effect, the solution appears not much less implicit and arbitrary in the problem.

The learned author of the theory, therefore, found himself under a necessity to solve the phenomena of his solution; and with this view, he presented the following hypothesis. The external parts of the globe he considers as the shell, and the internal as a nucleus, or inner globe; and between the two, he conceives a fluid medium. That inner earth, having the same common centre and axis of diurnal rotation, may turn about with our earth each twenty-four hours. Only the outer sphere having its turbinating motion some small matter either swifter or slower than the internal ball; and a very minute difference in length of time, by many repetitions, becoming sensible; the internal parts will, by degrees, recede from the external; and not keeping pace with one another, they will appear gradually to move either callward or westward, by the difference of their motions.

Now, suppute such an internal sphere, having such a motion, the two great difficulties in the former hypotheses are easily solved; for if this external shell of earth be a magnet, having its poles at a distance from the poles of diurnal rotation, and if the internal nucleus be likewise a magnet, having its poles in two other places, distant also from the axis; and these latter, by a gradual and slow motion, change their place in respect of the external, we may then give a reasonable account of the four magnetic poles aforesaid, as likewise of the changes of the needle's variation.

The period of its motion being wonderfully great, and there being hardly a hundred years since these variations have been duly observed, it will be very hard to bring this hypothesis to a calculus; especially since, though the variations do increase and decrease regularly in the same place, yet in different places at no great distance, there are found such casual changes thereof, as can no ways be accounted for by a regular hypothesis; but seem to depend upon the unequal and irregular distribution of the magmatic matter within the substance of the external shell, or coat of the earth, which deflect the needle from the position it would acquire from the effect of the general magnetism of the globe. Of which the variations at London and Paris give a notable instance; for the needle has been continually about $14^\circ$ more eastward at Paris than at London; though it be certain that, according to the general effect, the difference ought to be the contrary way; notwithstanding which, the variations, in both places, do change alike.

Hence, and from some other things of like nature, it seems plain, that the two poles of the external globe are fixed in the earth: and that if the needle were wholly governed by them, the variations thereof would be always the same, with some irregularities, upon the account just now mentioned. But the internal sphere having such a gradual translation of its poles does influence the needle, and direct it variously, according to the result of the attractive or directive power of each pole, and, consequentially, there must be a period of the revolution of this internal ball, after which the variations will return again as before. But if it shall in future ages be observed otherwise, we must then conclude that there are more of these internal spheres, and more magnetic poles, than four; which, at present, we have not a sufficient number of observations to determine, and particularly in that vast Mar de Zur, or South sea, which occupies to great a part of the whole surface of the earth.

If, then, two of the poles be fixed, and two moveable, it remains to ascertain which they are that keep their place.

The author thinks it may be safely determined, that our European north pole is the moveable one of the two northern poles, and that which has chiefly influenced the variations in these parts of the world; for, in Hadlon's Bay, which is under the direction of the American pole, the change is not observed to be near so fall as in these parts of Europe, though the pole be much farther removed from the axis. As to the south poles, he takes the Asiatic pole to be fixed, and, consequently, the American pole to move.

This granted, it is plain that the fixed poles are the poles of this external shell, or cortex, of the earth; and the other the poles of the magnetic nucleus, included and moveable within the other. It likewise follows, that this motion is westwards, and, by consequence, that the aforesaid nucleus has not precisely attained the same degree of velocity with the external parts in their diurnal revolution; but so very nearly equals it, that, in $565$ revolutions, the difference is scarcely sensible. That there is any difference of this kind arises, hence, that the impulse by which the diurnal motion was imprest upon the earth, was given to the external parts; and from thence, in time, communicated to the internal; but not so as yet perfectly to equal the velocity of the first motion imprest upon, and still conferred by, the internal poles. As to the consequence, we shall reserve it.

As to the precise period, we want observations to determine it, though the author thinks we may, with some reason, conjecture, that the American pole has moved westward $46^\circ$ in ninety years, and that the whole period thereof is performed in about seven hundred years.

Mr. Whilton, in his "New Law of Magnetism," raises several objections against this theory. See Magnetism.

M. Euler, the son of the celebrated geometrician of that name, has also controverted and cenfrued the above theory; he thinks that two magnetic poles placed on the surface of the earth will sufficiently account for the variation; and he then endeavours to shew, how we may determine the declination of the needle, at any time, and on every part of the globe, from this hypothesis. But we must refer for the particulars of this reasoning to the Histoire de l'Academie Royale des Sciences et Bellles Lettres of Berlin, for 1757.

Various other theories have been suggested by later authors; but most of these have been already alluded to under our articles Magnetism, Dipping-Needle, &c. We shall, therefore, here conclude this article, by referring the reader for a more minute account of the various theories, particularly that of Coulomb, to Haîry's "Elementary Treatise on Natural Philosophy," translated by Gregory, and to the first chapter of the third volume of Dott's "Traité de Physique."
VARIATION.

Variation or Declination of the Needle. To observe the—

Draw a meridian line, as directed under Meridian, then, a style being erected in the middle of it, place a needle thereon, and draw the right line which it hangs over. This will the quantity of the variation appear.

Or thus: as the former method of finding the declination cannot be applied at sea, others have been thought of, the principal of which follow: suspend a thread and plummet over the compasses, till the shadow paseth through the centre of the card; observe the rhumb, or point of the compasses, which the shadow toucheth when it is the shortest. For the shadow is then a meridian line; consequently the variation is shown.

Or thus: observe the rhumb in which the sun, or some star, rises and sets; bisect the arc intercepted between the rising and setting; the line of bisecting will be the meridian line; consequently the declination is had as before. The same may be had from two equal altitudes of the same star, observed either by day or night.

Or thus: observe the rhumb in which the sun, or a star, rises and sets; and from the latitude of the place find the eastern or western amplitude, for the difference between the amplitude, and the distance of the rhumb observed, from the eastern rhumb of the card, is the variation fought.

Or thus: observe the altitude of the sun, or some star, and the sun, S 1 (Plate II. Navigation, fig.) whose declination is known; and note the rhumb in the compass to which it then corresponds. Since, then, in the triangle ZPS, we have three sides; viz. PZ, the complement of the elevation of the pole PR; SP, the complement of the declination DS; and ZS, the complement of the altitude SI; the angle PZS is found by spherical trigonometry; the contiguous one to which, viz. A Z S, measures the azimuth HI. The difference, then, between the azimuth, and the distance of the rhumb observed from the south, is the variation fought. See Azimuth Compass.

Note, to have the eastern or western amplitude accurately, regard must be had to the refraction. See Refraction.

For the more commodious observing in what rhumb of the compass the sun, or a star, is seen, it will be proper to have two little apertures, or glass windows, opposite to each other, under the limb of it, with a telescope-fight fitted to one of them, and to the other a fine thread.

The use of the variation is to correct the courses a ship has feared by the compasses: e.g. given the course and the variation of the compasses, and let it be required to find the true course the ship fleaves: if the variation is west, call the N.W. quarter the 1st, the S.W. the 2d, the S.E. the 3d, and the N.E. the 4th; but if the variation be east, call the N.E. quarter the 1st, the S.E. the 2d, the S.W. the 3d, and the N.W. the 4th. Then, if the course be set in the 1st or 3d quarters, add the variation to the points or degrees in the given course; but if in the 2d or 4th quarters, subtract, and the sum, in the former, or the difference in the latter case, will be the course corrected by the variation.

Variation of Curvature, in Geometry, is used for that inequality, or change, which happens in the curvature of all curves, except the circle. And this variation or inequality constitutes the quality of the curvature of any line.

Sir Isaac Newton makes the index of the inequality or variation of curvature, to be the ratio of the fluxion of the radius of curvature to the fluxion of the curve: and Mr. Macaulin, to avoid the perplexity that different notions, connected with the same terms, occasion to learners, has adopted the fame definition; but he suggests, that this ratio gives rather the variation of the ray of curvature, and that it might have been proper to have measured the variation of curvature rather by the ratio of the fluxion of the curve itself to the fluxion of the curve; so that the curvature being inversely as the radius of curvature, and, consequently, its fluxion as the fluxion of the radius itself directly, and the square of the radius inversely, its variation would have been directly as the measure of it, according to Sir Isaac Newton's definition, and inversely as the square of the radius of curvature.

According to this notion, it would have been measured by the angle of contact contained by the curve and circle of curvature, in the same manner as the curvature itself is measured by the angle of contact contained by the curve and tangent. The reason of this remark may appear from this example. The variation of curvature, according to Sir Isaac Newton's explication, is uniform in the logarithmic spiral, the fluxion of the radius of curvature in this figure being always in the same ratio to the fluxion of the curve; and yet, while the spiral is produced, though its curvature decreases, it never vanishes, which must appear a strange paradox to those who do not attend to the import of Sir Isaac's definition. Newton's Meth. of Flux. and Inf. Series, p. 76. Macaulin's Fluxions, art. 386. Phil. Trans. N° 468. sect. 6. p. 342.

The variation of curvature at any point of a conic section, is always as the tangent of the angle contained by the diameter that passes through the point of contact, and the perpendicular to the curve at the same point, or to the angle formed by the diameter of the section, and of the circle of curvature. Hence the variation of curvature vanishes at the extremities of either axis, and is greatest when the acute angle, contained by the diameter, passing through the point of contact and the tangent, is leaft.

When the conic section is a parabola, the variation is as the tangent of the angle, contained by the right line drawn from the point of contact to the focus, and the perpendicular to the curve. See Curve.

Variation of Ratios. In the investigations of the relation which varying and dependent quantities bear to each other, conclusions are frequently more readily obtained by expressing only two terms in each proportion, than by retaining the four. But although in considering the variation of such quantities two terms only are expressed, it will be necessary to bear constantly in mind that four are supponed, who will lead the operations by which our conclusions are in this case obtained, are in reality the operations of four proportions.

1. One quantity is said to vary directly as another, when their magnitudes depend wholly upon each other, and in such a manner, that if the one be changed, the other is changed in the same proportion; thus, let A and B be mutually dependent upon each other in such a way, that if A changes to any other value a, B is changed to another value b, such that A : a :: B : b; then A is said to vary directly as B, which is denoted by the symbol of general proportion ∞ placed between the two quantities. Thus, for example, while the latitude of a triangle remains constant, the area varies directly as the base, or the area ∞ base; or for the base be increased or diminished, the area is increased or diminished in the same proportion.

2. One quantity is said to vary inversely as another, when it cannot be changed in any manner, but the reciprocal of the other is changed in the same proportion. A varies inversely as B, or A ∞ 1/B, if when A is changed
to \(a\), \(B\) is changed to \(b\), in such a manner, that
\[
A : a = \frac{1}{b} ; \quad \text{or} \quad A : a = b : B.
\]

For example, if the area of a triangle be given, the base varies inversely as the perpendicular altitude; for let \(A\) and \(a\) represent the altitude of two triangles of equal areas, and \(B\) and \(b\) their two bases; then
\[
\frac{A \times B}{2} = \frac{a \times b}{2} ; \quad \text{or} \quad A \times B = a \times b ;
\]
therefore,
\[
A : a = b : B ; \quad \text{or} \quad A : a = \frac{1}{b} = \frac{1}{B}.
\]

3. One quantity is said to vary as two others *jointly*, if, when the former is changed in any manner, the product of the two quantities is changed in the same proportion: that is, \(A\) varies as \(B\) and \(C\) jointly, or \(A \propto BC\), when \(A\) cannot be changed to \(a\), but \(BC\) is changed to \(bc\), such that
\[
A : a = BC : bc.
\]
The area of a triangle, for example, varies as the base and altitude jointly; for let \(A\), \(P\), \(B\), represent the area, perpendicular, and base of one triangle, and \(a\), \(p\), \(b\), the corresponding quantities in another; we know that
\[
A = \frac{1}{2} PB, \quad \text{and} \quad a = \frac{1}{2} pb ; \quad \text{consequently} \quad A = \frac{pB}{a},
\]
or \(A : a = PB : p\).

4. One quantity is said to vary *directly* as a second, and inversely as a third, when the first cannot be changed in any manner; but that the second, multiplied by the reciprocal of the third, is changed in the same proportion. That is, \(A\) varies as \(\frac{B}{C}\), or \(A \propto \frac{B}{C}\), when \(A : a = \frac{B}{C} ; \quad A, B, C, \text{and} \ a, b, c\), being corresponding values of these quantities.

For example, the base of a triangle varies as the area directly, and as the altitude inversely; for as in the preceding example,
\[
\frac{PB}{a} = \frac{A}{p} ;
\]
we multiply both sides by \(P\), we have \(\frac{B}{a} = \frac{pA}{Pa}\), whence \(B : a = \frac{a}{P} : \frac{p}{P}\).

The following are some of the principal propositions relating to the ratio of variable quantities.

If \(A \propto B\), and \(B \propto C\); then \(A \propto C\).
If \(A \propto B\), and \(B \propto C\); then \(A \propto C\).
If \(A \propto B\), and \(B \propto C\); then \(A \propto BC\).
If \(A \propto B\), and \(a \propto B\); or \(A \propto B\).
If \(A \propto a\), and \(M \propto m\); then \(A \propto a\).
If \(A \propto BC\); then \(B \propto AC\), and \(C \propto B\).
If \(A \propto B\), and \(C \propto D\); then \(A \propto B\).

Wood's Algebra.

Variation, Calculus of, is a department of the modern analysis, which we owe, as a distinct branch, to the inventive genius of Lagrange, who published his first memoir on this subject in the second volume of the Transactions of the Academy of Sciences at Turin, in 1762; and his second memoir, published in the fourth volume of the same Transactions, in 1770, gave to this theory a perfection and generalization far beyond what it was supposed capable of possi-

This method was also in the interval illustrated in the most simple and elementary manner by the celebrated Euler, in the Memoirs of the Academy of Sciences at Petersburg for 1764, as it was afterwards in the third volume of his Calcul Integral, and again in the Acta Petro-}

for 1771. Since that time it has been treated of by different authors at greater or less extent; and to Mr. Woodhouse, of Cambridge, we are indebted for a very neat little volume, in which this subject is handled in a very clear and conspicuous manner, from which work we have already given a few extracts under the article Isoperimetry. Boffut, also, in vol. ii. of his "Traités de Calcul Différentiel et de Calcul Intégral," has a very perpicious chapter on the calculus of variations, of which we shall avail ourselves in the present influence.

Let there be any indefinite expression or function compounded of variable and constant quantities, which changes its value by the increase or diminution of one or more of the elements which it contains: it will thus undergo a variation, and the method of finding this is what is called the *calculus of variations*.

In the same manner as \(x\) is made to denote the fluxion of \(x\), and \(\frac{d}{dx}\) the differential of \(x\); so \(\frac{dy}{dx}\) is used to indicate the variation of \(y\). The fundamental rules of this calculus are founded on the same principles as those of the differential calculus: at the same time, however, it is necessary to guard against confounding the one with the other. A very simple example will shew clearly the distinction that must be made between the two cases.

Let us suppose the equation \(y^2 = ax\), which denotes the relation between the absciss \(A\) and \(P\), and ordinates \(M\) and \(R\), of a parabola \(AM\) (Plate XIII. Analysis, fig. 1), \(a\) being the parameter. By drawing \(p, m\) indefinitely near to \(P, M\), and \(r, r\) parallel to the axis \(AV\); the line \(Pr, M\), will represent the differential \(dx\) and \(R\), the differential \(dy\); and the relation of these differentials is found by the differentiation of the equation \(y^2 = ax\), which gives

\[
\frac{2y}{dy}\frac{dy}{dx} = a + \frac{dy}{dx} \frac{dy}{dx} = \frac{a}{2y}.
\]

Let us conceive now that the equation \(y^2 = ax\), vary by the indefinitely small augmentation of its parameter \(a\), which is one of its elements; and let us construct a second parabola \(AN\), which has \(a + \frac{da}{dx}\) for its parameter. Then supposing the absciss \(A\) to continue the same for both parabolas, it is obvious that theordinate \(P\), of the parabola \(AN\), will have for its value the primitive ordinate \(PM\), augmented by the small quantity \(MN\), which therefore represents the variation that the ordinate \(PM\) undergoes in consequence of the variation of the parameter \(a\); hence, in representing by \(\delta y\) the variation of \(y\), as that of \(a\) is denoted by \(\delta a\), the new equation will be \((y + \delta y)^2 = \left(a + \delta a\right)x\); from which subtracting the original equation \(y^2 = ax\), we shall have (neglecting, as in the differential calculus, the variations of the second order)

\[
2y\delta y = \delta a, \text{or} \frac{\delta y}{y} = \frac{\delta a}{2y} \quad \text{or} \quad \frac{\delta y}{\delta a} = \frac{1}{2y}.
\]

Let us conceive that the equation \(y^2 = ax\), vary by the indefinitely small quantity \(P\), \(\delta x\), the corresponding ordinate for the parabola \(AN\), will be \(\delta n\), and the line \(sn\) will represent the variation of the primitive ordinate \(PM\). Now to find the relation between the variations \(\delta a, \delta x, \delta y\), we must substitute in the equation \(y^2 = ax\), \((a + \delta a)\) for \(a, \)
VARIATION.

\( (x + \beta x) \) for \( x \), and \( (y + \beta y) \) for \( y \), and the equation becomes

\[ (y + \beta y)' = (a + \beta a) (x + \beta x); \]

from which subtracting \( y^2 = ax \), we shall have

\[ 2y \beta x = x \beta a + a \beta x; \]

therefore,

\[ \beta y = x \beta a + a \beta x; \]

\( \frac{\beta y}{2y} = \frac{x \beta a + a \beta x}{2y} \]

which is an expression for the variation \( \beta \), of the ordinates \( P \).

In this example, (and the same has place for all similar equations,) the parameter \( a \), and its variation \( \beta a \), are constant quantities for the entire parabolas, while those of the co-ordinates \( P \) and \( A \) continually change; the changes, therefore, relative to the same parabola belong to the differential calculus, and those which result from the passage of one parabola to another, to the calculus of variations. Any one of the variations \( \beta a, \beta x, \beta y \), may be arbitrarily assumed; as, for example, we may suppose \( \beta x = dx \), but this supposition being once made, the values of the other variations must be subordinate to this, and we cannot therefore afterwards make \( \beta y = dy \), or \( \beta a = da \).

There is no difficulty in determining the variations of every order for algebraical and circular quantities, and common exponentials; the operations being exactly the same as in the differential calculus; we therefore obtain the variations by the same rules, and have only to write \( \delta \) instead of \( d \), and in this respect the calculus of variations returns again to the differential calculus; but this latter will not be sufficient when it is required to determine the variation of the formula, which contain in themselves the sign of integration: thus, for example, let the integral formula be \( \int V \, dx \), where \( V \) is any function of \( x \), \( y \), and \( z \), and constant quantities; we determine this by omitting the sign \( \int \), that is, \( \int \left( \frac{d}{dx} \, dx \right) = V \, dx \); but the expression \( d \int V \, dx \) is very different, as we shall see in what follows.

Now the principal object of the calculus of variations, is to determine the variation of these sorts of integral formulae; let us, therefore, endeavour to establish the principles which are to serve as the basis of this research.

First Principle.—The variation of a differential is equal to the differential of a variation, and reciprocally; that is, we shall have

\( \delta \frac{d}{dx} = \frac{d}{dx} \delta \).

For let us suppose that the variable \( \tau \) represents the ordinate of a curve; then this ordinate will change by differentials while it belongs to the same curve, and by variations in passing from the proposed curve to the curve indefinitely near to the first. In the primitive curve, let \( \tau' \) be the confecutive value to \( \tau \), and consequently \( \tau'' = \tau + \delta \tau \), or \( \tau = \tau - \delta \tau \). Now taking the variation of this last equation, we shall have

\[ \delta \tau = \delta \tau' = \delta \tau + \delta \delta \tau; \]

and in the same manner, as \( \delta \tau \) and \( \delta \tau' \) are confecutive values in the series of \( \delta \tau \), we may consider \( \delta \tau \) and \( \delta \tau' \) as confecutive values in the series of \( \delta \delta \tau \), so that \( \delta \tau'' = \delta \tau + \delta \delta \tau \), or \( \delta \tau = \delta \tau' = \delta \tau'' = \tau = \tau - \delta \tau \). Thus in equating these two values of \( \delta \tau'' - \delta \tau \), we shall have

\[ \delta \tau = \delta \tau'' \]

Hence if we have an expression which contains any number of \( d \)'s and \( \delta \)'s affecting one and the same variable, we make these particularities change place at pleasure; for we have seen that \( \delta d \tau = d \delta \tau \); and in the same manner, we may for \( \delta d \delta \tau \) write \( d \delta d \tau \), or \( d \delta \delta \tau \); and for \( \delta d \delta \tau \) we may write \( d \delta d \delta \tau \), or \( d \delta \delta d \tau \), or \( \delta d \delta \tau \), and so on of others.

Second Principle.—The variation of an integral formula is equal to the variation of its differentials; that is, \( \delta \int f \, dx = \int \delta f \, dx \).

Vol. XXXVI.
VARIATION.

If now we put for \( dy, \ d\rho, \ dq, \ dr, \ &c. \) their values
\[ p\ dx, \ q\ dx, \ r\ dx, \ s\ dx, \ &c. \] we shall find
\[
\begin{align*}
N \ dx (\partial y - \partial x) + P \ dx (\partial q - \partial x) + \\
Q \ dx (\partial r - \partial x) + R \ dx (\partial s - \partial x) + &c.
\end{align*}
\]
Consequently our equation (A) becomes
\[
\begin{align*}
\int V \ dx &= V \ dx + \int N \ dx (\partial y - \partial x) + \\
&\quad + P \ dx (\partial q - \partial x) + Q \ dx (\partial r - \partial x) + \\
&\quad + R \ dx (\partial s - \partial x) + &c.
\end{align*}
\]
This being established, let us make \( \partial y - \partial x = \delta w, \) (a substitution that will be employed in what follows,) and differencing, we shall have
\[
\begin{align*}
\partial \delta y - \partial \delta x = \delta \delta w.
\end{align*}
\]
But the formula \( \delta y = \delta \delta x \) gives, by taking the variations,
\[
\begin{align*}
\delta \delta y &= \delta \delta x \partial q + \partial \delta \delta x, \text{ or} \\
\delta \delta y &= \delta \delta x \partial q + \partial \delta \delta x, \text{ or} \\
\delta \delta y &= \partial \delta \delta x = \partial \delta \delta x.
\end{align*}
\]
Whence, making the necessary substitutions, we obtain finally
\[
\begin{align*}
\int V \ dx &= \int V \ dx + \int N \ dx (\partial y - \partial x) + \\
&\quad + \int P \ dx (\partial q - \partial x) + \int Q \ dx (\partial r - \partial x) + \\
&\quad + \int R \ dx (\partial s - \partial x) + &c.
\end{align*}
\]
a formula in which \( dx \) is supposed constant.

It will be seen from this expression for the variation \( \partial \int V \ dx, \) that it includes two distinct orders of terms, the one affected with the sign \( \partial \), and the other free from it. And farther, that the integration by parts necessarily introduces certain constant quantities which must be annexed

\[
\begin{align*}
\int V \ dx &= \int V \ dx + \int N \ dx (\partial y - \partial x) + \\
&\quad + \int P \ dx (\partial q - \partial x) + \int Q \ dx (\partial r - \partial x) + \\
&\quad + \int R \ dx (\partial s - \partial x) + &c.
\end{align*}
\]

Whence, by substitution, we have
\[
\begin{align*}
dx \partial \rho - d \partial \rho x = d \partial w.
\end{align*}
\]
Now putting for \( \partial \rho \) its equivalent \( q \ dx, \) we shall have
\[
\begin{align*}
dx \partial \rho - q d \partial x x = d \partial w, \text{ or} \\
\partial \rho - q \partial x = \frac{d (\partial y - \partial x)}{dx}.
\end{align*}
\]
and as the quantity \( \partial \delta \) has for its value \( \delta y - \partial x, \) by hypothesis we have again \( \partial \rho - q \partial x x = \frac{d (\partial y - \partial x)}{dx}. \) And a calculation exactly similar to the preceding gives also,
\[
\begin{align*}
\partial q - r \partial x x = \frac{d (\partial q - \partial x x)}{dx}, \\
\partial r - s \partial x x = \frac{d (\partial r - \partial x x)}{dx}, \quad \text{etc.}
\end{align*}
\]
Consequently the equation (B) becomes
\[
\begin{align*}
\int V \ dx &= V \ dx + \int N \ dx (\partial y - \partial x) + \\
&\quad + \int P \ dx (\partial q - \partial x) + \int Q \ dx (\partial r - \partial x) + \\
&\quad + \int R \ dx (\partial s - \partial x) + &c...(C)
\end{align*}
\]
Now by the method of integrating by parts, we find, by making \( dx \) constant,
\[
\begin{align*}
\int \frac{d^2 \delta w}{dx^2} &= \int \frac{d^3 \delta w}{dx^3} + &c.
\end{align*}
\]
to the terms of the latter species. The aggregate of the terms affected with the sign \( \int \) extends through all the variation, \( \text{viz.} \) from its commencement to its termination, while the other quantities answer only to the beginning and end of the variation. This remark finds its application in treating of the maxima and minima of quantities.

PROB. III.

To determine the variation of the indefinite compound integral \( \int V \ dx, \) \( Z \) being a given function of the indefinite simple integral formula \( \int V \ dx, \) where again \( V \) is a function of \( x, y, z, \rho, q, r, \&c. \) as in the preceding problems.

First by Prob. I.
\[
\begin{align*}
\int Z \ dx = Z \ dx + \int (d x \partial Z - d Z \partial x) \ldots (E)
\end{align*}
\]
And supposing \( \int V \ dx = t, \) or \( V \ dx = d t; \) since \( Z \) is by hypothesis a function of \( t, \) we shall have \( d Z = T \ dt, \) \( T \) being a given function of \( t, \) and we shall thus have \( d Z = T \ dt; \) therefore
\[
\begin{align*}
dx \partial Z - d Z \partial x = T d x \partial t - T d t \partial x.
\end{align*}
\]
Consequently we have
\[
\begin{align*}
\int Z \ dx = Z \ dx + \int T d x \partial (d x \partial Z - d Z \partial x) \ldots \ldots \ldots \ldots \ldots (F)
\end{align*}
\]
Now integrating the last term by parts, and representing the integral \( \int T d x \) by \( b, \) for the sake of abridging the preceding equation becomes (F)
\[
\begin{align*}
\int Z \ dx = Z \ dx + b \int (d x \partial V - d V \partial x) = b \int (d x \partial V - d V \partial x).
\end{align*}
\]
This
VARIATION.

This being premised, and making here the values for the variables $dV$ and $\delta V$ the same suppositions, and the same calculations as in the preceding problem, we shall obtain

$$h \frac{dV}{dx} = \int \frac{dV}{dx} \delta x,$$

and hence we draw, by a proceeding similar to that which has been employed in the second problem,

$$dZ \delta x = L' \left( dV \delta x - dV \delta x \right) + N' \delta x \left( \delta y - \delta x \right) + P' \delta x \left( \delta y - \delta x \right) + Q' \delta x \left( \delta y - \delta x \right) + R' \delta x \left( \delta y - \delta x \right) + \&c.$$
If now, as in the second problem, we make
\[ \frac{dV}{dx} = M \frac{dy}{dz} + N \frac{dz}{dx} + P \frac{dp}{dz} + Q \frac{dq}{dz} + \&c. \]
we shall have
\[ dV = M dy + N dz + P dp + Q dq + \&c. \]
substituting, in equation \((K)\), instead of \(f \frac{dV}{dx} (dx) \delta V - dV dx \), its actual value \( f \frac{dV}{dx} (dx) \delta V - dV dx \), and instead of \( dV dx \delta V - dV dx \), the value assumed above, reuniting the several parts, and for the sake of abridging, making \( L'N + N'' = N, L'P + P'' = P' \), we have \( V = V' \) \&c.: this equation will become
\[ \frac{\delta}{\delta} V dx = Z dx + f \left\{ N'' dx (2y - p \delta x) + P'' dx (p - q \delta x) \right\} \]
\[ + Q'' dx (3q - r \delta x) + R'' dx (3r - s \delta x) + \&c. \}
\[ = Z dx + f \left\{ N'' dx (2y - p \delta x) + P'' dx (p - q \delta x) \right\} \]
\[ + f Q'' dx (3q - r \delta x) + f R'' dx (3r - s \delta x) + \&c. \]
An equation which, being of the same kind as Equation \((B)\), Prob. II. will give in the same manner, by making \( \delta y - p \delta x = \delta w \), and supposing \( dx \) constant,
\[ \frac{\delta}{\delta} V dx = \]
\[ \frac{dV}{dx} dx = \]
\[ \frac{dV}{dx} dx = \]
\[ \frac{dV}{dx} dx = \]
Substituting, in equation \((K)\), instead of \(f \frac{dV}{dx} (dx) \delta V - dV dx \), its actual value \( f \frac{dV}{dx} (dx) \delta V - dV dx \), and instead of \( dV dx \delta V - dV dx \), the value assumed above, reuniting the several parts, and for the sake of abridging, making \( L'N + N'' = N, L'P + P'' = P' \), we have \( V = V' \) \&c.: this equation will become
\[ \frac{\delta}{\delta} V dx = Z dx + f \left\{ N'' dx (2y - p \delta x) + P'' dx (p - q \delta x) \right\} \]
\[ + Q'' dx (3q - r \delta x) + R'' dx (3r - s \delta x) + \&c. \}
\[ = Z dx + f \left\{ N'' dx (2y - p \delta x) + P'' dx (p - q \delta x) \right\} \]
\[ + f Q'' dx (3q - r \delta x) + f R'' dx (3r - s \delta x) + \&c. \]
An equation which, being of the same kind as Equation \((B)\), Prob. II. will give in the same manner, by making \( \delta y - p \delta x = \delta w \), and supposing \( dx \) constant, we shall have, by precisely similar operations to those performed in Prob. II.
\[ \frac{\delta}{\delta} V dx = \]
\[ \frac{dV}{dx} dx = \]
\[ \frac{dV}{dx} dx = \]
\[ \frac{dV}{dx} dx = \]
\[ \frac{dV}{dx} dx = \]
Now let \( \delta y - p \delta x = \delta w \), and \( \delta z - p' \delta x = \delta w' \); and supposing \( dx \) constant, we shall have, by precisely similar operations to those performed in Prob. II.
\[ \frac{\delta}{\delta} V dx = \]
\[ \frac{dV}{dx} dx = \]
\[ \frac{dV}{dx} dx = \]
\[ \frac{dV}{dx} dx = \]
\[ \frac{dV}{dx} dx = \]
To which it will be necessary to add certain terms, in order to complete the integral, as stated in the conclusion of our second and last problem.

The formulae above considered are the simplest of their kind, and the solution of them is found by a calculation comparatively direct and easy to perform; but it may happen, that in the general expression \( f \frac{dV}{dx} (dx) \), of which the variation is required, the quantity \( V \) is a function of many variables, conflating of algebraical expressions and various indefinite simple integrals; or the quantity \( V \) may depend upon the integration of an equation of any order; it may also, in some cases, be required to find the variation of a formula under a double
VARIATION.

a double or triple, &c. sign of integration, as \( \int \int Z \, dx \, dy \), in which \( Z \) is any function of \( x \) and \( y \), and so of others. In all these cases, except the last, the variations are determined in the same manner, but the calculus of course becomes more long and intricate, which our limits will not allow of our entering upon in this place. On this head, therefore, the reader is referred to the several works mentioned in the introduction to the present article. We only propose giving here one problem, by way of illustrating the preceding calculations; viz.

To determine the curve \( O \, M \, D \) (Plate XIII. fig. 2) through which a body will pass from the point \( O \) to \( D \), not in the same vertical line, in the shortest time possible.

Let \( A \, V \) represent the vertical plane, in which are situated the two given points \( O \) and \( D \); \( A \, V \) the axis of the absciss; and the horizontal line \( A \, F \) that of the ordinates. Also, let us suppose any absciss \( A \, P = x \), the ordinate \( P \, M = y \), and consequently the element of the arc \( M \, m = \sqrt{d x^2 + d y^2} \), making \( d \, y = \rho \, d \, x \).

Now whatever may be the nature of the curve \( O \, M \, D \), the velocity of the body along and in the direction of the element of the curve \( M \, m \), is equal to that with which it would have acquired in falling from a certain vertical height; all these heights deriving their origin in the same horizontal line, which we may suppose to be the axis of the ordinates \( A \, Z \), the position of this axis being arbitrary.

Thus, calling \( g \) the gravity of the body, the velocity along \( M \, m \) will be \( \sqrt{2 \, g \, x} \), and consequently the time in passing \( M \, m \) will be \( \frac{M}{\sqrt{2 \, g \, x}} \); therefore we shall have

\[
\int \frac{d \, x}{\sqrt{(1 + \rho^2)}} = a \text{ minimum},
\]

or, simply

\[
\int \frac{d \, x}{\sqrt{(1 + \rho^2)}} = a \text{ minimum}.
\]

Now generally, when a quantity becomes a maximum or a minimum, its variation is equal to zero; consequently we shall have

\[
\frac{d}{d \, x} \sqrt{(1 + \rho^2)} = 0.
\]

Now this agrees with our formula \( \int V \, dx \) in the second problem; viz. in the present case \( V = \sqrt{(1 + \rho^2)} \); consequently we shall have \( d \, V = \frac{\sqrt{(1 + \rho^2)}}{2 \, x} \cdot d \, x + \frac{\rho}{\sqrt{(1 + \rho^2)}} \cdot d \, x \); an expression which, being compared with the general value

\[
d \, V = M \, d \, x + N \, d \, y + P \, d \, \rho + \&c.
\]

gives here

\[
M = -\frac{\sqrt{(1 + \rho^2)}}{2 \, x \, \sqrt{(1 + \rho^2)}}; \quad N = 0; \quad P = \frac{\rho}{\sqrt{(1 + \rho^2)}}; \quad Q = 0; \quad R = 0, \quad \&c.
\]

Now the expression of the variation \( \frac{d}{d \, x} \int V \, dx \) comprehends generally, as we have seen in Equation (D), two parts, the one indefinite, containing the sign \( \int \) and the other definite, in which that sign is not found; and it is evident that these two parts are wholly independent of each other; and consequently, if the whole is equal to zero, these two parts are each also equal to zero; thus the equation \( \frac{d}{d \, x} \int V \, dx = 0 \), gives in general the two following equations, of which the one is definite, and the other indefinite; viz.

\[
(1) \quad \int V \, dx + \int P \, d \, \rho = 0
\]

\[
\int \frac{d}{d \, x} \left( P \frac{d \, Q}{d \, x} + d \, \rho \frac{d \, R}{d \, x} + d \, \rho \frac{d \, \rho}{d \, x} \right) = \&c.
\]

(2) \[ \int V \, dx + \int P \, d \, \rho = 0 \]

\[
\int \frac{d}{d \, x} \left( Q - d \, \rho + \&c. \right)
\]

\[
+ \frac{d \, \rho}{d \, x} \left( R + \&c. \right)
\]

\[
+ \&c. + C, \quad \text{correction}.
\]

Equation (1) is that on which depends the nature of curves, since the second member of this equation is an indeterminate expression, which being made equal \( \alpha \), gives to the curve \( O \, M \, D \) the character of a maximum or a minimum. As to Equation (2), it belongs only to the extreme points of the curve \( O \, M \, D \), which may be subject to particular conditions, wholly independent of the nature of the curve.

Now differentiating Equation (1), and dividing the whole by \( d \, x \), we shall have

\[
(3) \quad \int \frac{d \, P}{d \, x} + \int \frac{d \, Q}{d \, x} + \int \frac{d \, R}{d \, x} = 0
\]

which gives generally the solution of the problem, where only the nature of the curve is required, that renders \( \int V \, dx \) a maximum, or a minimum; \( V \) being a function of the perpendicular co-ordinates \( x \) and \( y \) of the curve, and of the quantities \( p, q, r, \&c. \) which are given by the hypothesis \( d \, y = \rho \, d \, x \), \( d \, p = q \, d \, x \), \&c. remembering that the differential \( d \, x \) has been supposed constant.

Now to apply these general results to our problem; since we have \( N = \alpha \), and \( P = \frac{\rho}{\sqrt{(1 + \rho^2)}} \); also \( Q = c \), \( R = \alpha \), \&c. our Equation (3) becomes

\[
(3) \quad \int \frac{d \, P}{d \, x} + \int \frac{d \, Q}{d \, x} + \int \frac{d \, R}{d \, x} = 0
\]

which is the differential equation of the curve \( O \, M \, D \); consequently, by integrating we shall have

\[
\frac{\rho}{\sqrt{(1 + \rho^2)}} = \frac{1}{\sqrt{a}} \cdot a \text{ being an arbitrary constant quantity.}
\]

Now sublimate for \( \rho \) its value \( \frac{d \, y}{d \, x} \) and we shall have

\[
\frac{d \, y}{\sqrt{x} \cdot \sqrt{(1 + \rho^2)}} = \frac{1}{\sqrt{a}} \cdot \frac{d \, y}{d \, x}
\]

which gives

\[
d \, y = \frac{d \, x}{\sqrt{x} \cdot \sqrt{a - x}}.
\]

the equation of the referred cycloid, its base being horizontal, and its generating circle having for its diameter the constant quantity \( a \).

This equation being integrated, will receive a second arbitrary constant \( b \); and we shall have then, in the final equation, two constants, \( a \) and \( b \), which will be determined from the condition that the cycloid passes through the two points \( O \) and \( D \).
O and D, given in position. For other examples illustrative of this calculus, see the article ISOPERIMETRY.

VARIATION, in Music, is the different manner of playing or singing the same air, tune, or song, either by subdividing the notes into several others of less value, or by adding graces, in such a manner, however, as that the tune itself may still be discovered through all its embellishments, which the French call broderies.

Thus, great matters of the last century, flattering the bad taste of the public, have condescended to make variations to old tunes; as Corelli to Farinel's ground, or "All Joy to great Cecar," which the Italians call "La Follia d'Epangna," and which he has made the theme of his whole twelfth sonata. Handel and Tartini have composed simple airs on purpose to be the ground-work of variations. The late John Christian Bach, Fichter, Giardini, &c. have varied Scotch and Irish tunes to corrupt the public taste, instead of improving it by new compositions, which would have done them more credit, and given them less trouble. See Theme and Double.

"All Paris," says Ronseuff, "used to go to the concert spiritual, to hear the variations of Meffrs. Guignon and Mondionville; and still at a more recent period, those of Meffrs. Guignon and Gaviniès, to the tunes of the Pont-neuf, which had no other merit than that of being tried with by the two greatest performers on the violin in France?"

VARICA, in Ancient Geography, a town of Atlantic Iberia, according to Ptolemy.

VARICELLA, in Medicine, a diminutive of Variola, (the small-pox,) signifying a vehicular eruption, accompanied with flight febrile symptoms, and occurring but once in the period of human life, which is popularly termed chicken-pox and swine-pox. It will not be matter of surprize if this disease should bear the name of a lesser small-pox, and that it should have been described by the older writers as a modification of that distemper, under various similar appellations, such as varicella purulenta, volatiles, puraris, &c.; when we are informed by a late acute investigator of diseases, Dr. Willan, that, from the year 1800, to the time of the publication of his effay on vaccination, in 1806, he had been seventy-four cases of chicken-pox that had been mistaken for small-pox, after vaccine inoculation. It is true, indeed, that the distinction has been rendered somewhat more difficult, in consequence of the milder degree, shorter duration, and modified form, which the small-pox itself has been made to assume by the influence of the previous cow-pox, in the few cases where it has occurred after this disease. Nevertheless, the resemblance is sufficient at all times to mislead ordinary observers; and the foreign nomenclature, from Sauvages down to Burlerius, have considered the disease as a species of variola. (See Sauvages Nofol. Method. clafs iii. gen. 2. Vogel, De Cognitione et Curand. Hominum Morbis, § 126. Burlerius, Infl. Med. vol. ii. cap. 9.) It is singular, however, that not only some of the earlier Italian writers on the small-pox, who lived three centuries ago, have distinctly described the chicken-pox under a specific name, erythall, and with the mention of the fearfully perceptible fever, and absence of all danger (see Vindicus Vindicis, De Cyntheticis; and Ingraffia de Tumoribus præter Naturam, lib. i. cap. 1.) but that the vulgar, in several countries of Europe, had distingusihed it by popular appellations, even while physicians were regarding it as a modification of small-pox. Thus Daniel Sennert, who was a professor at Wittemberg at the commencement of the seventeenth century, observes, in his Trestifé on Small-pox and Measles, that there are other varieties, "præter communes variolas et morbillas," which are popularly known in Germany by the terms schaffbistellen (sheep-pox, or sheep-blows or blains) and windkolten (wind-pox). (See his Med. Præct. lib. iv. cap. 12.) And Rivierius, who was professor at Montpellier at the same period, speaks of it as familiarly known by the common people in France by the name of veirodette. (See his Praxis Med. cap. ii.) In Italy it was also known to the vulgar under the appellation of ravigione. Again, in our country, Fuller, who published his "Examen Medici" in 1730, acknowledges himself indebted to the old women for his appellation. "I have adventured to think," he says, "this is what among our women goeth by the name of chicken-pock." (P. 161.) Other popular names have been given to the disease in different parts of this country. Thus it is in many places called swine-pox; in some, horse-pox; and at Sunderland and Berwick, water-jugy. (See Dr. Wood in the Med. and Phys. Journal, vol. xiii. p. 58.) In some places, however, the different forms which the disease itself assumes, three of which have been distinctly described by the late ingenious Dr. Willan, are designated by the terms chicken-pox, swine-pox, and hives, respectively.

The character of each of these varieties, under which the varicella occasionally appears, we shall copy from the work of that excellent observer of diseases, as there is no other description of them extant of equal accuracy; and it is highly necessary to be able to discriminate between this eruption and the milder forms of small-pox, and especially that modified and altered varicella which sometimes succeeds vaccination. The only other account of the chicken-pox in our language, which bears the stamp of observation, is a paper of the late excellent Dr. Heberden, another physician of the true Hippocratie school, written in the year 1767, and published in the first volume of the Transactions of the College of Physicians, and which we shall have occasion also to quote, on the point of diagnosis, in the sequel of this article. Dr. Willan observes, "there are three varieties of the varicella, which, from the different forms of the vehicles, may be entitled the lenticular, conoidal, and globate." And he adds, in a note, "In the northern parts of England, and in some counties of Scotland, these varieties are denominated the chicken-pox, the swine-pox, and the hives. In the south, both the latter varieties are called swine-pox.

1. "The lenticular varicella exhibits, on the first day of eruption, small red protuberances, not exactly circular, and having a flat shining surface, in the centre of which a minute vehicle is soon formed. This, on the second day, is filled with a whitish lymph, and it then somewhat resembles a milky vehicle, but is not so prominent, so tenue, or so regularly circumcised: its diameter is about the tenth of an inch. On the third day, the extent of the vehicles continues the same, but the lymph they contain becomes straw-coloured. On the fourth day, many of the vehicles are broken at the most prominent part; the red begin to shrink, and are puckered at their edges. Few of them remain entire on the fifth day, but the orifices of several broken vehicles are closed, or adhere to the skin, so that it is not confined to the affected skin, but spreads to the adjacent parts. On the sixth day, small thin brown fleas appear universally in the place of the vehicles. The fleas, on the seventh and eighth days, become yellowish, and gradually dry from the circumference towards the centre. On the ninth and tenth days they fall off, leaving for a time red marks in the skin, without depression.

2. "In the conoidal varicella, the vehicles rise suddenly, and have a hard inflamed border. They are, on the first day of their
VARICELLA.

The appearance, acuminated, and contain a bright transparent lymph. On the second day they appear somewhat more turbid, and are surrounded by more extensive inflammation than on the preceding day; the lymph contained in many of them is of a light straw-colour. On the third day, the vesicles are shrivelled; those which have been broken exhibit at the top, a gummy fluid, and have much inflammation round them, evidently contain on this day purulent fluid. Every vesicle of this kind leaves, after scabbing, a durable cicatrix or pit. On the fourth day, thin dark-brown vesicles appear intermixed with others, which are rounded, yellowish, and semi-transparent. These vesicles gradually dry and separate, and fall off in four or five days.

"A fresh eruption of vesicles usually takes place on the second and third day, and as each vesicle has a similar course, the whole duration of the eruptive phase in this species of varicella is six days; the last-formed vesicles, therefore, are not separated till the eleventh or twelfth day."

3. "In the swine-pox, or hives, the vesicles are large and globated, but their base is not exactly circular. There is an inflammation round them, and they contain a transparent lymph, which, on the second day of eruption, refumbles milk-whey. On the third day, the vesicles subsides, and, as in the two former species, become puckered or shrivelled. They likewise appear yellowish, a small quantity of pus being mixed with the lymph. Some of them remain in the same state till the following morning, but, before the conclusion of the fourth day, the cuticle separates, and thin blackish vesicles cover the bases of the vesicles. The vesicles dry and fall off in four or five days.

"The eruption is usually completed in three days, but I have sometimes observed a few fresh vesicles on the fourth day; in which case, therefore, the eruptive phase occupied eight days.

"The fever in varicella commences two or three days before the eruption appears, and it sometimes continues to the third day of the eruption, but is generally very slight. Its symptoms are languor, with disposition to sleep, loss of appetite, thirst, heat of the skin, occasional flushing of the cheeks, a severe cough, foreheads of the throat, a white fur on the tongue, a quick but unequal pulse, pains in the head, back, and limbs, sometimes pain in the loins and bowels, with nausea, or vomiting of bile.

"The eruption usually commences on the breast and back, appearing next on the face and neck, and lastly on the extremities. It is attended, especially in children, with an incessant tingling or itching, which leads them to scratch off the vesicles, so that the characteristics of the disease are often destroyed at an early period. Many of the vesicles, thus broken and irritated, but not removed, are presently surrounded by inflammation, and afterwards become pustules, containing thick yellow matter. These continue three or four days, and finally leave pustes in the skin. The eruption is usually fullest in the conoidal form of varicella: I have seen the vesicles close together, or coherent, but seldom confluent. When they are numerous on the scalp, tume of the glands below the base of the cranium are enlarged.

"The incidental appearance of pustules among the vesicles sometimes occasions a doubt respecting the nature of the eruption. See Dr. Willan's "Treatise on Vaccination," page 86.) Dr. Heberden says, "the principal marks by which the chicken-pox is distinguished are:

1. The appearance, on the second or third day from the eruption, of the vesicles full of serum upon the top of the pock. The pustules which are full of the yellow liquor resemble what the genuine small-pox are on the fifth or sixth day, especially when there happens to be a larger space than ordinary occupied by the extravasated serum. It happens to most of them, either on the first day that the little vesicle arieres, or on the day after, that its tender cuticle is burst; a thin scab is then formed at the top of the pock, and the swelling of the other part abates, without its ever being turned into pus, as it is in the small-pox.

2. "Small scabs cover the chicken-pox on the fifth day; at which time the small-pox are not at the height of their suppuration.

3. "The inflammation round the chicken-pox is very small, and the contents of them do not seem to be owing to suppuration, as in the small-pox, but rather to what is extravasated immediately under the cuticle by the ferox vesicles of the skin, as in a common blister. No wonder, therefore, that this liquid appears so soon as on the second day, and that upon the cuticle being broken, it is presently succeeded by a light scab. Hence too, as the true skin is so little affected, no mark or scar is likely to be left." See Med. Trans. of the Coll. of Physicians, vol. i. art. 16.

To these remarks Dr. Willan adds, that "various pustules, on the first and second day of their eruption, are small, hard, globular, red, and painful. The sensation of them to the touch, on passing the finger over them, is similar to that which one might conceive would be excited by the pressure of small round seeds under the cuticle. In the varicella almost every vesicle has, on the first day, a hard, inflamed margin, but the sensation communicated to the finger in this case, is like that from a round seed, flattened by pressure." He also observes that, "on the third and fourth days, the shrivelled or wrinkled state of the vesicles which remain entire, and the radiating furrows of others, whose ruptured apices have been closed by a slight incrustation, fully characterize the varicella, and distinguish its eruption from the firm and durable pustules of small-pox. As the vesicles of the chicken-pox appear in succession during three or four days, a partial examination will not always discover the characteristic here specified. In order to form a proper judgment, practitioners should inspect the eruption on the face, breast, and limbs, attending more especially to the places in which it was first observed. If the whole eruption be viewed on the fifth or sixth day, every gradation of the progress of the vesicles will appear at the same time. This circumstance may be added to the diagnosticks of varicella, as it cannot take place in the slow and regulated progress of the small-pox.

"The globulated vesicles not having any resemblance to various pustules, distinguish the varicella from the small-pox, whenever they appear; for it is to be remembered, that these large vesicles are occasionally intermixed, both with the lenticular and conoidal vesicles of the chicken-pox. It may be said, that an acknowledged co-existence of different sets of vesicles in the same person tends to abrogate the distinction I have made. The vesicles, however, are, in many cases, all of the same kind: or, where they are intermixed, one sort greatly predominates. I do not contend for the perfect accuracy of nosological arrangement, but I adopt it because it is in many respects convenient. Systems of botany and zoology are useful, though they have not been yet brought to perfection, for we find some species which break the order of every classification proposed." Loc. cit. p. 96.

With respect to the treatment of varicella, under any of its forms, very little need be said: since it is seldom attended by any feverish indisposition, and often by scarcely any perceptible disorder of any of the functions, except a little malaise and inability for the usual exertions, a whiff of the tongu,
tongue, and some loss of appetite. In these cases, the
medical recommendation is rather in avoiding all causes of irritation,
such as the use of hot, spicy foods, than in the actual administra-
tion of medicines. Where the fever is more considerable,
however, not only are these cautions necessary, but it will
be proper also to evacuate the bowels, by gentle means, as
by a little rhubarb, or neutral salts, to take dilute drinks,
and gently diaphoretic medicines.

VARICOCELE, in Surgery, derived from varix, a di-
lated vein, and καλα, a tumour, sometimes denotes a varico-
ence enlargement of the veins of the spermatheic cord; but, more
commonly, a similar diffuse enlargement of the veins of the
scrotum; the term cirrocele being usually applied to the other affec-
tion.

Varicocele, or a varicoce enlargement of the veins of the
scrotum, is a subject of but little importance; because
these vessels are never thus affected, except in consequence of
some other more serious disease of the testicle and its
surroundings. Indeed the varicocele is to be regarded as the
more effective cause of the disease, not merely on account of
the only necessary indication, but of the effects of the disease, which
being never self-sustaining, a source of much inconvenience, always subsides without fur-
ther trouble.

Varicocele, considered as a varicoce enlargement of the
spermatheic veins, is a disease that demands greater attention;
but as it has been explained in a previous volume (see Cir-
socelle), we do not mean to detain the reader with it in the
present place. One remark, however, appears to merit par-
ticular attention: a varicoce swelling of the spermatheic veins
is more frequently than any other disease mistaken for an
omental hernia. Mr. Askley Cooper has given the following
rule, by which the two diseases may be distinguished: Place
the patient in a horizontal posture, and empty the swelling by
premature upon the scrotum; then put the fingers firmly upon
the upper part of the abdominal ring, and defcribe the patient
as follows: if it be a hernia, the tumour cannot disappear as
long as the pressure is continued at the ring; but if it be a
cirrocele, the swelling returns with increas’d force, on account
of the return of blood into the abdomen being prevented by
the pressure. See Cooper on Inguinal Hernia.

VARICOSE VEINS. The term varix is applied by
surgeons to the permanently dilated tube of a vein, attended
with an accumulation of dark-coloured blood, the circulation
of which is materially retarded in the affected vessel. When
veins are varicose, they are not only dilated, but they are also
evitably elongated, preternatural larger than nat-
ural, irregular, and in several places fluided with knots. They
likewise make a variety of windings, and, coiling themselves,
form actual tumours from the assemblage of their convolu-
tions in one particular place. The trunk and branches of a
vein, thus dilated and elongated, constitute a very distinct
swelling, when they are numerous, and confined to a certain
part of the body. Indeed, when the diseased vessels are
situated near the integuments, the surgeon can feel, and even
see the outlines of their tortuous course. These things, for
instance, are remarkably obvious in the vein saphenous interna,
where the affection is particularly common. This vein may
be observed to form in its course several of these swellings,
in the interstices of which it runs in a very serpentine tor-
thous manner.

Varices are most commonly observed in the lower extremi-
ties, reaching sometimes even as far up as the abdomen. They
have, however, been noticed in the upper extremities, and it is
probable that the whole venous system is susceptible of the
affection. As a well-informed writer observes, "the great
venous trunks sometimes become varicose. When the diseased
vein is situated near the heart, it is attended with pulsation, which
renders it liable to be mistaken for aneurism. Morgagni ob-
served that the jugular veins were occasionally very much dil-
ated, and pollexed a pulsation. (Letter xviii. art. 9. fo. 11.) He
also relates a case in which the vena azygos, for the length of
a span, was so much dilated, that it might be compared with
the vena cava. The patient died suddenly in con-
sequence of the rupture of this varix into the right side of the
heart. (Letter xxvi. art. 29.) A similar case is related by
Portal, who also mentions an instance, in which the right
subclavian vein was excessively dilated, and burst into the
heart. (Cours d’Anatomie Medicale, tom. iii. pp. 354-373.) Mr. Cluets, in his lectures on the circulatory system of a woman
who had a large pulsating tumour in her neck, which burst, and
proved fatal by hemorrhage. A case reported from the in-
ferior jugular vein; the carotid artery was lodged in a
groove at the posterior part of this face. The veins of the
upper extremity very rarely become varicose. Excepting
cases of aneurismal varix, the only influence of this disease
which I am acquainted with mentioned by Petit. (Traté
sur l’Hypertrophie des Veines de la Céphalée, tom. p. 49.) In this case a varix was
situated at the bend of the arm; the patient was too fat, that
no other vein could be found for the purpose of vene-
fication, which operation Petit repeatedly performed by
puncturing this varix. The superficial epigastric veins sometimes
become varicose; but the most frequent seats of this
disease are the vena saphena, the spermatheic and hemorrhoidal
veins.” (See Hodgson’s Treatise on the Diseases of Ar-
teries and Veins, pp. 538, 539.) The deep-seated veins of the
extremities seldom become varicose.

The disease rarely occurs before the adult period of life,
and its progress is extremely slow. It is very frequently
marked in pregnant women, who have a fat called age;
but it is particularly usual for it to happen in young
women, even during a series of repeated pregnancies. Suc-
urgeons have not hitherto made out any very precise informa-
tion respecting the places, climates, and kinds of constitut-
ions which promote the occurrence of a varicoce enlarge-
ment of the veins. Nor has it been well proved, that the
disease often proceeds from swellings of the abdominal vasaer,
and with other species of tumours capable of mechanically ob-
instructing the venous circulation. One or more veins of the
same limb are at first most commonly affected with a slight
degree of dilatation, without pain, or any sensation of un-
cahnese. This beginning change ordinarily advances with
great swiftness, except in cases where it accompanies preg-
nancy, in which circumstance one or both the lower extre-
mities, as early as the first month, are frequently seen co-
verted with largely dilated veins, or even with tumours formed
by an assemblage of varices. The veins gradually become
more and more distended, lengthened, coiled up, and tor-
uous. The patient then begins to complain of a sense of heaviness, numbness, and sometimes of very acute wandering
pain through the whole of the affected limb. In a more ad-
vanced stage, in proportion as the varices increafe, and espe-
cially when the dilated veins actually form tumours, the limb
swells, and becomes more or less aedematous, according to
the extent of the diseaee, and the time which it has exifled.
M. Delpech thinks, however, that the aedema in this case is
not such as to justify the conclusion, that the increased size of
the veins, and the way in which they distend the integu-
men, produce a mechanical interruption of the function of the
absorbent system. For, says he, we meet with, though not often, enormous varices, which are not attended
with any swelling of the cellular substance; and we still
more frequently fee caffes, in which there is a considerable
degree of aedema, while the varices are scarcely remarkable.
When the latter have prevailed a long while, and made much

much progress, the coats of the affected veins are not frequently thickened, swelling, and indurated, forming a fort of half canal, or solid tube, which has been regarded as an excavation made by the preasure of the varix against the neighbouring bone. But the same phenomena are equally observable, when varicose veins lie at a distance from any bone, against which it can be prefixed.

As Mr. Hodgson remarks, "the blood occasionally deposits fibrings of coagulum in varicose veins: when this is the cafe, the vessel is incapable of being emptied by preasure, and is firm to the touch. The depoition does not in general fill the vessel, but, by diminishing its calibre, it retards the flow of blood, and causes the dilatation to increase in the inferior portion of the vein, and in the branches which open into it." (On the Diseases of Arteries and Veins, p. 541.) This gentleman has seen four cafes, in which the coagulum accumulated to such an extent, that the canals of the dilated vessels were obliterated, and a spontaneous cure was the consequence.

The excessive dilatation of the coats of a superficial vein produces an inflammatory irritation, at first in the adjoining cellular membrane, and afterwards in the integuments. These organs become at first connected together by the adhesive inflammation; and if the dilatation continue to operate, they may at length ulcerate, and burst, and hemorrhage be the consequence. In such cafes, the effusion of blood has sometimes been very considerable; but, says M. Delpech, we have no example of its having proved dangerous. The syncope following it, or a moderate compression, has sufficed for its stoppage. A more common occurrence than bleeding, is the coagulation of the blood in the cavity of a varicose vein. The vessel then becomes hard and incompressible, and it loses that elastic yielding tofheen, which renders it capable of being diminished by gentle pressure. If the parts be already infamed, Delpech conceives, that the clot in the diseased vein may act as an extraneous body, and bring on ulceration, by the effects of which it is as laft brought into view. In this sort of cafe, it is extremely uncommon for hemorrhage to occur; for, in general, the vessel has been already obliterated by the preceding inflammation. But the ulcer itself is very difficult to heal, and may be kept up a long time by the edematous swelling of the limb. Varices, or rather the edema which is the consequence of them, has the fame effect upon every other species of ulcer, and even upon the moft simple solution of continuity. When the swelling of the limb cannot be dispersed; while the edges of a solution of continuity are kept affurer by the taut flate of the skin; and while the divided parts are irritated by this painful tension; every thing is unfavourable to cicatrization. Thus we see the moft simple wounds, which have been allowed to suppurate, and ulcerate, which should have healed rapidly, continue uncurc a great many years, merely because the limbs, on which they are situated, are affected with an edematous swelling, the consequence of varices. Such is the condition of things in the cafe which has been improperly named the varicose ulcer. Delpech Traité des Maladies Chir. tom. iii. feét. 8. art. 5.

In the investigation of the causes of varices, it is usual to dwell very much upon the mechanical obstructions which may affect the circulation of the blood in the veins. Surgeons have thought themselves justified in regarding this as the only cause, because a circular, moderate compression incontrollable retards the course of the blood in these vessels, and produces a temporary dilatation of them. The opinion has seemed also to derive confirmation from the knotty appearance of varicose veins, a circumstance which has been accounted for by supposing, that the dilatation is greatest in the situation of the valves. Lastly, the idea is further supported on the well-known fact of the frequent occurrence of varices during the slate of pregnancy. But it has not been remembered, that the use of garters, for example, is extremely common; but varices are not very frequent; that very large varices are met with in persons who have never employed any kind of ligatures, to which the origin of the complaint can be imputed; that when the dilatation of the veins extends to the thighs and parts of the abdomen, no causes of this description even admit of suspicion; that varicose veins are observable round several kinds of tumours, especially firrхи; when there is no possibility of pointing out any mechanical obstruction to the circulation of the blood; that varices sometimes make their appearance at the commencement of pregnancy, and long before the enlargement of the womb can impede the free return of the blood through the veins in the pelvis; that nothing is more unusual than a varicose dilatation of the veins of the lower extremities, in consequence of swellings of the abdominal vessels. Lastly, it has been forgotten that the knots of the dilated veins are far too numerous to admit of being ascribed to the resistance of the valves. It cannot be denied, that pressure applied in the track of the vessels, tends to promote their dilatation; but it can neither be considered as the only cause, nor as the principal one. The foregoing observations made by Delpech, render it probable, that some unknown general cause is concerned in producing varices, the formation of which may also be facilitated by the impediments to the free return of the blood, occasioned by certain attitudes, and particular articles of clothing.

Mr. Hodgson conceives it probable, that in some instances, the valves are ruptured in consequence of mucular exertions, or external violence, in which cafes, the pressure of the column of blood is the first cause of the dilatation of the veins. Sometimes, also, the disease appears to arise from preternatural weaknesses in the coats of the veins, as in those instances in which, without any evident cause, it exists in various parts of the same person. Treatise on the Diseases of Arteries and Veins, p. 537.

Experience proves, says Delpech, that there is no certain mode of curing varices, strictly so called, which he thinks cannot be wondered at, since the nature and causes of the diseafes are completely unknown. The same source of knowledge, however, also proves, that the increase in the dilatation of varicose veins may be retarded, and that the edematous swelling attendant on the complaint may be beneficially opposed. But these effects cannot be produced by rofesolvent, tonic, astringent applications, nor by aperient, diuretic, and purgative remedies, as soe even of the latest writers so inconsiderately assert; but only by means of mechanical and permanent compression. When the whole of a limb affected with varices is subjected to this laft mode of treatment, the dilated veins subside, the circulation is more regularly performed, and the edema and pain cease. There is not, says Delpech, any better method of healing the solutions of continuity in the soft parts produced or kept up, by the varicose flate of the limb and its consequences. But as soon as the compression is discontinued, the varices make their appearance again, the pain recurs, the edema reappears, and the ulcers which were healed break out afresh. Compression, therefore, which absolutely required to be constantly employed, can be regarded only as a palliative, the more useful indeed, inasmuch as the changes which it brings about in the state of things are nearly equivalent to a perfect cure.
Inflammation of the integuments covering a varix, or varicofe tumour, cannot invariably be prevented by compression, nor will this treatment always succeed even in removing the intolerable pain which sometimes attends numerous clusters of varicofe veins. In the first case, rest and relaxing applications will often succeed; and in the second, the topical use of sedatives frequently gives relief. It has been proposed to puncture and empty varicofe veins; but if a temporary emptiness and relaxation of these vessels, which are rendered painful by their dilatation, could remove the pain for a time, things would fall into the old state again in the course of a few days. If it should appear also, that the clotted blood had the effect of keeping up the unfavourable symptoms, it would be necessary to make a very considerable opening into the dilated vein, in order that the coagulum might be extracted. In such a case, it would be useless to tie the vessel above and below the opening, as has been recommended: the slightest compression is afterwards sufficient for the stoppage of the bleeding, and by the subsequent inflammation the vessel is certain of being obliterated.

We learn from Celsus, that the ancients were accustomed to remove varices by excision, or destroy them with the cautery. (De Rê Médica, lib. vii. cap. 3.) When the vein was much convoluted, extirpation with the knife was preferred; but in other cases, the dilated vessel was excised by an incision, and then cauterized. Petit, Boyer, and many surgeons in this country, have also sometimes practised the operation of cutting out clusters of varicofe veins.

Delpech remarks, that the extirpation of tumours composed of numerous varices, has been practised either for the purpose of removing the pain in the situation of the diseafed, or other inconveniences. "This operation has been successfully performed; but it appears also not to have conftantly had the effect of preventing the formation of new varices, and it has sometimes proved tedious, difficult, and severely painful in its execution. In fact, an erroneous judgment must necessarily be formed of the extent of these swellings, when they are judged of only from the appearance which they present under the skin. When we attempt to operate, says Delpech, we may be led to organs which ought not to be meddled with, and a long and extremely painful dissection may be found requisite. Besides, varices are not always confined to the superficial veins, and a relapse would be inevitable. These reflections tend to the conclusion, that operations of this sort should never be undertaken, except when the diseafed is accompanied with perilous symptoms, or nearly deprives the patient of the use of his limb."

It has been thought, that one of the established principles in the treatment of aneurism might be advantageously extended to the cure of varicofe veins. By tying the principal venous trunk above the point to which the varicofe affection reaches, it is said that the course of the blood in the morbid vessels may be totally stopped; the column of this fluid contained in them made to coagulate; and the consequent obliteration of the vessels themselves accomplished.

The practice of tying veins for the cure of varices appears to have been employed in the days of Paré and Dionis, (Cours d'Opérations de chirurgie, p. 610.) who have accurately described the operation of tying and dividing the vein between the two ligatures. Sir Everard Home has related many cases of varicofe veins in the leg, some of them being accompanied with tedious ulcers, in which, after tying the vena faphena major, where it passes over the inside of the knee, not only the dilatation of the veins of the leg was relieved, but the ulcers were readily healed. This proceeding has unquestionably been sometimes followed with success; but it has also had its failures. Amongst other evils, an inflammation of the tied vein has been observed extending very far in the vessel, and succeeded by convulsions and death. Indeed, the dangers arising from an inflammation of the internal coat of the veins are now generally acknowledged, and every endeavour should be made to avoid them. A case which lately happened in one of the large hospitals of this metropolis, has fully proved them: we allude to the example, in which the femoral vein happened to be wounded in the operation for aneurism, and had a ligature applied round the small aperture accidentally made in it. Inflammation of its internal coat took place to a considerable extent, and the patient is supposed to have died of the indifiopon resulting from it.

As Mr. Brodie observes, it seems to be now established by the experience of modern surgeons, that a mechanical injury inflicted on the trunk of one of the larger veins, is liable to be followed by inflammation of its internal membrane, and a fever of a very serious nature; and the occasional occurrence of these symptoms after the ligature, or even the simple division of the vena faphena, has made surgeons less confident than formerly, of the propriety of attempting these operations for the relief of a varicofe state of the branches of that vessel in the leg. Certain reflections, however, induced Mr. Brodie to think, that the same ill effects would not follow a similar operation performed on the branches themselves. "Where the whole of the veins of the leg are in a state of morbid dilatation, and the difficulties produced by the diseafed is not referred to any particular part, there seem to be no reasonable expectations of benefit, except from the uniform pressure of a well-applied bandage. But not unfrequently, we find an ulcer which is irritable, and difficult to heal, on account of its connection with some varicofe vessels; or without being accompanied by an ulcer, there is a varix in one part of the leg, painful and perhaps liable to bleed, while the veins in other parts are nearly in a natural state, or at any rate are not the source of particular uneafiness. In some of these cases, I formerly applied the caufic potash, so as to make a flough of the skin and veins beneath it; but I found the relief which the patient experienced from the cure of the varix, to afford but an inadequate compensation for the pain to which he was subjected by the use of the caufic, and the inconvenience arising from the tedious healing of the ulcer, which remained after the separation of the flough."

"In other cases, I made an incision with a scalpel through the varix and skin over it; this destroyed the varix as completely as it was destroyed by the caufic, and I found it to be preferable to the use of the caufic, as the operation occasioned less pain, and as, in consequence of there being no los of subflance, the wound was cicatrizd in a much shorter space of time. I employed the operation, such as I have described it, with advantage in several instances; but some months ago I made an improvement in the method of performing it, by which it is much simplified, rendered less formidable, not only in appearance, but also in reality; and followed by an equally certain, but more speedy cure."

"It is evident," says Mr. Brodie, "that the extensive division of the skin over a varix, can be attended with no advantage. On the contrary, there must be a disadvantage in it, as a certain time will necessarily be required for the cicatrization of the external wound. The improvement to which I allude consists in this; the varicofe vessels are completely divided, while the skin over them is preferred entire, with the exception of a moderate puncture, which is necessary for the introduction of the instrument with which the incision
incision of the veins is effected. Thus the wound of the internal parts is placed under the most favourable circumstances for being healed, and the patient avoids the more tedious processes, which is necessary for the cicatrization of a wound in the skin above.

For this operation, I have generally employed a narrow sharpened bistoury, slightly curved, with its cutting-edge on the convex side. Having ascertained the precise situation of the vein, or cluster of veins, from which the diffeats of the patient appears principally to arise, I introduce the point of the bistoury through the skin on one side of the varix, and pass it on between the skin and the vein, with one of the flat surfaces turned forwards, and the other backwards, until it reaches the opposite side. I then turn the cutting-edge of the bistoury backwards, and in withdrawing the instrument, the division of the varix is effected. The patient experiences pain, which is occasionally severe, but subsides in the course of a short time. There is always hemorrhage, which would be often profuse if neglected, but which is readily stopped by a moderate pressure, made by means of a compress and bandage carefully applied." Mr. Brodie particularly enjoins the necessity of keeping the patient quietly in bed for four or five days after the operation, and removing the bandage and flannel dressings with the utmost care and gentleness. He also cautions surgeons not to make the incision more deeply than absolutely necessary. Inflammation of the coats of the veins has not occurred in any of the cases in which Mr. Brodie has adopted this method of treatment. This gentleman wishes it to be understood, however, that he does not recommend the practice indiscriminately, but with the greatest attention to the circumstances of each individual case. "The cases for which it is fitted, are not those in which the veins of the leg generally are varicose, or in which the patient has little or no inconvenience from the complaint; but those in which there is considerable pain referred to a particular varix; or in which hemorrhage is liable to take place from the giving way of the dilated vessels; or in which they occasion an irritable and obdurate varicocele ulcer." See Medico-Chir. Trans. vol. vii. p. 195, et seq.

On the subject of cutting through veins affected with varix, it is proper to observe, that even this plan has been known to bring on severe and fatal symptoms. Cases confirming this fact are recorded in a valuable modern work, which should be in the hands of every practical surgeon. (See Hodgson's Treatise on the Diseaes of Arteries and Veins, p. 555, et seq.) It is but justice to state, however, that in these examples, Mr. Brodie's manner of doing the operation was not adopted.

As we have already noticed, cafes of spontaneous varix in the veins of the arm are rarely observed. When these vessels become varicose, it is almost always in consequence of a communication being formed, in the operation of venefication, between the brachial artery and one of the veins at the bend of the arm. The superficial veins in this situation then become more or less dilated by the impulse of the stream of arterial blood which is thrown into them. There is, however, a good deal of difference between those accidental varices actually induced by a mechanical cause, and those which originate spontaneously, or from caules not very clearly understood. The former never acquire the size which the latter often attain; they never exceed a certain magnitude, whether prefire be employed or not; they never form tumours composed of an assemblage of varicose veins; they are never filled with tough coagula of blood; their coats are never thickened, nor constitute the solid half canal remarked in the other species of varices; the skin which covers them is not disposed to inflame and ulcerate; they are not subject to occasional hemorrhage; and the limb is not affected with any edematous swelling. (See Delpech Traité des Maladies Chr. tom. iii. p. 261.) These circumstances must render it sufficiently evident that all surgical interference in such a case would be entirely unnecessary.

For additional observations connected with the subject of varicose veins, see the article AXERRUSIS, where the aneurismal varix is described; CHOSICLE, where the varix of the piformer cord is treated of; HEMORRHOIDS, where the diseased and enlarged veins of the rectum are considered; and VARICOLOGY, where those of the scrotum are noticed. Delpech Précis Éléméntaire des Maladies réputées Chirurgicales, tom. iii. Hodgson's Treatise on the Diseases of Arteries and Veins. Cooper's Dictionary of Practical Surgery.

VARICOSE Ulcer. See the preceding article, and Ulcers. VARICOSE, or Varicous, a term applied to a kind of soft puffy swelling, or particular sort of ulcer in animals, mostly about the legs. See Ulcers, in Animals.

VARICULA, (diminutive of varix,) in Surgery, a varicose enlargement and dilatation of the veins of the tunica conjunctiva of the eye; a frequent consequence of chronic inflammation.

VARIÉAS, in Geography, a town in Portugal, in the province of Beira; 14 miles S.E. of Lamengo.

VARIÉGATED LEAVES, in Botany and Vegetable Physiology, folia variegata, or more properly variaota, are such as are irregularly blotched with white or yellow, constituting a variety, for the most part permanent, and which are not uncommon in several species of shrubs, trees, or herbs. The white variegation is most usually seen in Elder, some kinds of Elm, Round-leaved Mint, or Mentha rotundifolia, and Striped Gras, or Phalaris arundinacea; the yellow one in Jamine, White Lily, and in many evergreens, as Holly, Rumus Alatus, Philyrea latifolia, Acuba japonica, and many others. We have seen an accidental, very beautiful, specimen, in Rumex oblongifolius, but it was not permanent. A romantic garden, among some very uncommon and whimsical rocks at Plumpton, near Harrogate, was originally planted with nothing but variegated shrubs, of every species that could be procured. It might have delighted a Chinoer, but the effect was not picturesque.

This change in the colour of leaves, more or less extended occasionally to the rest of the herbage, can be considered but as a sort of disease. The plants affected with it are much more tender, and difficult of cultivation, than in their natural state, as well as less luxuriant; and witness Antirrhinum Cymbalaria, Fritillaria imperialis, and many others. Variegated Oaks are rare, and fickle. We do not recollect to have seen any Willow in this state, nor any Cherry, Plum, Currant, or Gooseberry. The Holly assumes different shades of yellow, sometimes accompanied with pink. Prunus Lauro-cerasus now and then puts forth an entirely white or colourless shoot, and we have several times met with the same circumstance in Rosa canina, but we do not know that either of these shrubs is permanently variegated.

The cause of these blotches in leaves is probably among those secrets of Nature, hardly, if ever, to be discovered. That it must confine in some quality of the soil, in which the original stock vegetated, is a probable conjecture, but no more. The variety commonly continues unimpaired, in offsets or cuttings from this original stock, in whatever soil they may be planted. Nevertheless, a shrub thus marked, or defaced, will now and then, from luxuriance of health, return to the pristine and natural verdure of its species, making
making flocks of extraordinary vigour, which soon overtop and exclude the variegated parts of the same individual.

VARIETIES, in Natural History, a word used to express an accidental change in some body, which is not essential to it, and therefore does not constitute a different species.

The naturalists of former ages have run into great errors, in mistaking the accidental varieties of plants, animals, and minerals, for distinct species. Many of them have called a plant a new species, because its flower, which should have been blue or red, is white, on account of the poornefs of the foil, or some other such reason. Mr. Ray has established a very good rule for varieties in botany: he allows every thing to be a distinct plant, which will propagate itself in its own form by its seeds; but such as, when sown, lose their difference, and run back to the old standard, he accounts varieties, however great their distinctions may appear.

In the history of fish, as much confusion has been introduced, by mistaking varieties for distinct species, as in botany. Artedi is the only author who has rationally attempted to bring this part of natural history into order in this respect, and to settle regularly the rules by which to distinguish real and effential from accidental differences.

The principal grounds of the error of supposing varieties distinct species of fish have been these: the variable and inconstant colour of fish hath been mistaken for a specific difference; in this manner Rondelius has described many varieties of the turdi, labri, and other fish, under the names of distinct genera.

Others have paid the same too great a regard to the more constant varieties of colour, which are found only to differ in degree in the several individuals of the same species, and their differences to be only in the degrees of the same colour, which is much more intense in some, and more remits in others. These differences can only make varieties of the same fish, the species remaining always the same. Of the same kind are the mistakes of those who esteem size or magnitude a specific character; and thus, out of the varieties of the same fish, occasioned by scarcity or plenty of food, or other such occasions, make larger or smaller species. The place where fish are caught is also another cause of making new species with these authors: thus, though the perca fluviatils of Bellonius, and the perca marina of other authors, be the same fish, yet they are pretended to be different species. The time of spawning is also with some made a distinction of species; and thus we find the common pike divided into three species, according to its spawning, in spring, summer, and autumn, which it does according to the heat or coldness of the climate. See Specific Names.

All these differences are false and frivolous, and the utmost they can do is to make what are properly called varieties, though few of them are sufficient even for that. A salmon caught at sea is not different from one of the same breed caught in a river; and if the perca marina, falsely so called, be a little different from the perca fluviatils, yet if its spawn will produce regular perca fluviatils, its difference can only amount to a variety, not a distinct species.

The time of spawning is no essential difference: for we daily see the change of climate make changes of that kind in all creatures; and even in the same climate, and under the same circumstances, the same species of birds will afford some individuals much earlier or later in laying their eggs than others. Artedi Ichthyol.

Varieties, in Botany and Vegetable Physiology, are certain differences between individuals of the same species, which are not sufficiently important to constitute a specific dilution, nor, however important or striking, are they permanent, except in offsets, buds, cuttings, or layers of the same individual. Even these are oberved, sooner or later, to wear out; while, on the other hand, some varieties do appear to be continued, by seed, through successive generations, at least in annual plants; but a very flight degree of observation will shew that these gradually return to their original nature; sometimes very speedily. Varieties amongst edible fruits seem to be the most numerous and the most laffing; but whether they are more to others, which, being important to mankind, pafs unnoticed, as in the Pangur tribe, may be doubted. Mr. Knight, the learned and experienced President of the British Natural Society, has convinced himself, and we believe most of his intelligent readers, that varieties of Apples and Pears have only a limited duration. (See Species of Plants.) Thus the most valuable, perhaps, of all, the Golden Pippin, and particularly the ruffet-coated kind of that fruit, is generally wearing out. It may be propagated by grafting; but the young trees, thus obtained, quickly canker, and cease to bear any fruit worth notice. Numbers of Apples and Pears, celebrated in the horticultural works of the French, and many known to have exilted formerly in England, are no more to be found. Those who plant orchards draw out admirable plans upon paper, buy trees, and wait with great complacency for the produce, till they find themselves miserably deceived. Half their trees, poftibly, bear something different from what was promised. So far they have a right to complain of an ignorant, careless, or dishonest nurseryman. The greater part of their whole flock, whether the fruit be good or bad in quality, canker, turns mofly, or dies, in a few years. Some few hardy trees only, of ordinary fruits, perhaps remain. The foil is concluded to be unfit for apples, and the affisor bears his disappointment as well as he can. This is the literal history of several orchards, which have passed under our observation. We have also seen fine trees of Golden Pippins and Nonpareils, which twenty years ago bore full crops of excellent fruit, canker and die, without any apparent cause, so that the places which knew them, know them no more. Such is the melancholy history of our orchards. But it is still more grievous to observe, that new varieties, which Mr. Knight, and some other patriotic cultivators, are obtaining every year from seed, prove far more transient than their predecessors, cankering and disappearing in four or five years. Some, however, we hope and trust, will remain, and that our descendants will not be deftitute of the most valuable of all English fruits. With this important end in view, we cannot sufficiently recommend, to those who have the means, the razing of apple-trees from feed, every year, on a large scale. It has usually been the practice of such experimentists to fell the kernels of good apples, for their purpose; thinking such more likely to yield something analogous to their parent fruit. Perhaps they may inherit too much of the same constitution, and this may be the latent cause of their own short existence. Might it not be worth while to sow the seeds of healthy wild crab-trees, whose vigour might remain in their offspring? From such, doubtless, all our valuable varieties must, at first, have originated. Who can tell that the degeneracy so prevalent among the new-raifed stocks, as to duration, may not be owing to the repeated crossed impregnation of diseased worn-out varieties, which must take place in a garden? The ornaments of our courts and drawing-rooms may descend from the heroes of Cresly and Agincourt, but our modern heroes commonly rise from the ranks, and the quarter-deck.

In the ornamental department of horticulture, varieties are
are much attended to. Cape Geraniums are raised, by crosses impregnation, which often excel their parents in size and beauty, and for a while are continued by cuttings, if not by seed. Nothing, however, can be more transitory than these ephemeral productions. We have adverted to some of them under the article Pelargonium. Double-flowered varieties are produced from time to time, either by nature or by some accident of cultivation, for which we cannot in any manner account. Thus, if we sow an hundred seeds of the common Annual Stock, Cheliranthus annuus, one, or perhaps many, of the plants may bear nothing but completely double flowers, all the reef being quite single. When such a variety occurs in any perennial, or shrubby, species of plant, it is justly prized, being capable of multiplication by cuttings, layers, &c; and when variations of colour are superadded, as in the favourite Camellia japonica, the treasures of the conservatory are still more multiplied. We must be content, in the present state of knowledge at least, to seize each vegetable Proteus as it comes in our way, without attempting to explain, or to imitate, the cause of its transformation.

Colour is, of all things, most liable to vary in the petals of flowers. Almost every blue flower is capable of changing to white, and it appears that in several instances the seeds of the white variety more generally produce their like, than those of the natural-coloured flowers change to white. But this rule is not invariably. The seeds of Canterbury Bells, Campanula Medium, whether taken from a white or blue flower, appear, as far as we can judge, to produce a great majority of blue-flowered plants, with a few white ones. The elegant varieties of the Sweet Pea, Lathyrus odoratus, seem more constant; but they are comparatively of recent introduction amongst us, and it is probable they may in time wear out, like other more short-lived beauties.

Varieties in the luxuriance or flavour of annual herbs, or their seeds, which make the riches of a kitchen garden, require, of all things, the most affidious attention of a cultivator. These are the most casual and fugacious of all things. They do, however, appear to be more within the control of a skilful gardener, than many above-mentioned; especially with regard to soil, or manure. An eminent London seedman affirms the writer of this, that he found it expedient to feed lettuce seed to a remote country, the south of France, for influence, one seafon, and its produce to Holland, or Germany, perhaps, the next, in order to preserve or improve its quality. Change of crops every body knows to be essential in farming, as well as change of seed. What are the various degrees of excellence in Wheat, barley, or other grain, but varieties, in what possibly, when originally wild, refembled but an ordinary grafs. These excellencies are kept up by culture, that is, by attention to the circumstances just detailed. Such attention is infinitely more requisite in the cultivation of high-fed, pampered, and delicate culinary vegetables, which, if at all neglected, soon return to their original kind, or more frequently vanish altogether. Varieties of Peas, obtained by crosses impregnation, are a late improvement in horticulture, which promises a more durable success. For this acquisition to our tables we are indebted to the skilful and indefatigable exertion of Mr. Knight, who has also extended his philosophical inquiries and experiments to Strawberries. It is much to be wished that the tett of distinction between a variety and a species, which this gentleman has assumed, or rather adopted from animal phylologists, may hold good. This is, their power of generating together, without limitation. That unquestionably distinct species in the vegetable king-

dom will, like the horse and the ass, produce a mule; and that such mules will, for a longer or shorter period, continue to propagate themselves, as the animal mule is said occasionally to do, we cannot deny. It is sufficient for the preservation of order in nature, that such bastard progenies are limited; nor have we any doubt that, if they were all diligently watched, their termination, sooner or later, might always be observed. But we are not the less aware of the hazard of drawing conclusions on this subject, without a sufficiently long course of observation; analogy, always in philosophy to be followed with caution, being in the present case peculiarly treacherous.

In practical botany, varieties often cause no small trouble. Linneus was among the first who, upon found principles, distinguished them from species. Tournefort, and most of his followers, enumerated all the different appearances of plants that fell in their way, without regard to their permanency, or specific distinction. Hence a plant with a blue or a white flower stands, in the works of these authors, as two different species; though manifestly the same in every other character, and perhaps produced from seed out of one and the same capsule. Linneus blames Micheli for making sixteen species out of the common Dutch Clover. (See Trifolium repens.) Of these, some indeed prove more certainly distinct species than Linneus imagined; but the reef are, many of them, distinguished by casual marks, that may or may not exist, in the same individual plant, the following seafon. Some botanists contend that the red and the blue Lychnis dioica, so different in colour, must constitute two species. We have found the larger kind, which is usually white, with a pink flower, and thinking we had made a great acquisition, transplanted it into a garden. Next year the same root bore pure white flowers, and no others. All cultivators know how Tulips, Hyacinths, Anemones, and the garden Ranunculus, differ and vary in colour, from the same seed, and even on the same root at different seafons. The fame plant of Hydranga hortensis will produce pink or blue flowers according to the time of year, or the manner in which it is treated as to foil and watering. Bog-earth generally induces the blue tint. To multiply infinaces of this fort, would lead us beyond all bounds.

Pubescence has been thought to afford a good specific distinction, and in some cases it unquestionably does. Its direction is certainly very material, and has been applied by the writer of this to discriminate species of Menthe, as it has by Dr. Roth to establish distinct species of Myosotis. But the quantity of hairiness on a plant is very variable, and can hardly be laid to mark even a variety. A perfectly smooth wild plant of Mentha horiata, the calyx and flower-flake excepted, being transplanted into a garden, proved as hairy all over as any of its brethren, the very next seafon. On the subject of the specific characters, as opposed to mere varieties, we have already been sufficiently explicit, under the head Species of Plants, nor need we here add any further illustrations.

Some botanists, even of the present day, are curious to mark varieties under each species. This may on some occasions, and in gardening books, be useful; but if their specific distinctions be well founded, each variety will of itself fall into its proper place. To dwell upon them is a trilling study, except so far as their different qualities may lead to any practical utility; or their various origins and changes, to any physiological instruction. With the latter intention, the ingenious Mr. K. Brown has, for some time past, been attentive to every strange deformity or non-

fruity,
VARIETIES.

Varieties, in Gardening, the different variations of the fame general nature from that of the parent or particular fort from which they came. They are, of course, the offspring of certain peculiar determinate forts, which vary in some accidental particular of their habits of growth, or some other circumstance, from the natural original fort, or parent plant. But although this is the case, as their variations are, for the most part, confined to some particular part or parts, they still retain the specific mark or marks of distinction of the parent plant, which discriminates them from those of other different forts. Consequently there are frequently numerous varieties from the same fort, all of which differ from it, either in their manners of growth, foliage, flowers, the economical qualities which they possess, or some other particular of a similar nature. All kinds of plants, both of the annual, biennial, and perennial descriptions, as well as those of the herb and tree fort, are liable to vary in this way. This is effected by different modes and kinds of culture, by the nature of the climate, by that of the soil, by the use of particular forts of manure and other materials, by frequent changes in their situation, by age, and in many other methods, and respects their differences in size and magnitude, their luxuriant, dwarfish, erect or trailing growths, their being smooth or prickly; the nature and shape of their leaves, as broad, narrow, entire, divided, cut, spotted, variegated, round, oval, sharp, blunt, &c.; smooth, hairy, downy; in their flowers, as single, double, proliferous, white, red, blue, yellow, variegated, &c.; in their smell, as sweet-scented, rank-scented, &c.; also in the form, size, colour, taste, quality, &c. of the fruit, in some cases, as round, oval, oblong, smooth, furrowed, warted, hairy, downy, large, small, red, green, four, sweet, compact, pulpy, &c. as in the cucumber, melon, apple, pear, gooseberry, currant, &c.; likewise, in particular inlines, in the shape and appearances of the roots, as in the carrot, the radish, the turnip, the potato, &c.; in the manner of their producing their seeds, fruits, &c.; as in the hop, spinach, hemp, &c.; and the cucumber, melon, &c. And it takes place in many other circumstances.

However, notwithstanding these different modes of variation in the particular parts of the varying plants of a peculiar fort, if those of each such fort till all maintain the same specific mark of distinction as that which characterizes and discriminates the respective natural forts from all others, it flows them all the offspring, or varieties, of the same original fort. For as every different and distinct fort, in any particular kind of plants, is discriminated by some peculiar, uniform, constant mark or appearance in some part of its growth, all the plants of the same particular kind changeably bearing exactly the same, are, notwithstanding their accidental variation in other parts of their growth, all varieties of one fort. Consequently all the plants which are produced from the seed of the same particular fort, however they may put on different forms and appearances, are to be considered as the real varieties of it.

The difference betwixt any particular fort and that of a variety, is, that a really true fort, raised from seed, will, though it may sport into many variations, still retain and keep its true and invariable mark of distinction through all its varieties; and although there may be varieties of that particular fort with different sized leaves, and colours of the flowers, &c.; if the seed of any one be sown, it will probably produce young plants of all these kinds, each having the characteristic discriminating mark of the parent.

It is, indeed, in a great measure, from plants of the feeding kind, that the different varieties of particular forts were first obtained, as in the case of the auricula, polyanthus, &c. each being a distinct fort of the same kind, and each of which contains innumerable varieties, in the colours and variegations of the flowers, first gained in this way, the feed of the same plant often producing a great diversity in this respect, each variation of colour, &c. forming a real variety; but probably not one of them with a flower exactly like that of the original parent plant: yet each variety retains the specific difference of its respective particular fort, the auricula, for instance, never changing to the polyanthus, nor that to the auricula, but the varieties of each keep their proper distinction; as the auricula, in all its varieties, contains its smooth fleshy ferrated leaves; and the polyanthus, its rough-toothed leaves. And the same is the case with the carnation, the ranunculus, the anemone, the tulip, and a great number of other flower-garden plants.

The tree kind, especially those for the production of fruit, are particularly disposed to form varieties, equally in their modes of growth, their foliage, and the fruit: for instance, one original fort of apple-tree is only admitted, but which furnishes an almost endless variety of fruit, in regard to shape, fize, colour, taste, quality, &c. as well as in the growth of the trees, so far as respects their size or magnitude, the dimensions and colours of the foliage, &c.; the specific distinction of which is, ferrated leaves, and clofetttving flowers in the form of an umbel, which runs through all the numerous varieties, however different the trees may be in size, growth, leaves, and fruit. And the same takes place in the pear, the plum, the common cherry, the peach, and many others, there being only one principal fort of each of these, but the varieties of the fruit are many in number, which, in all these sorts of trees, were originally obtained from feeding plants, that is, such trees as were raised by setting the slips or kernels of the fruit. Almost all the fruit-tree kind sport greatly in their feeding plants, so that out of hundreds of trees raised from the seeds of the best fruits, very few, if any, will produce fruit exactly like that of the parent plant, or which possesses any good perfection. Therefore, on account of the uncertainty of producing and continuing the approved sorts of fruit from feeding plants, recourse is confantly necessary to be had, in the practice of gardening, to the modes of grafting, budding, and, in some inlines, the making of layers and cuttings, in order to propagate the intended and desired sorts, or to continue and increase any good newly acquired variety.

The greater number of varieties in herbaceous plants, as well as many kinds of fruit and other trees, are of a variable and sporting nature, so that when raised from seed, there is no dependence on having the feeding plants coming again of the same fort, but varying into different sorts of one another. In cafes of this nature, the propagation of such of them as
are perennial, to continue them with certainty, is to be accomplished either by means of planting their suckers, or the offsets or slips of the roots, and in some by layers and cuttings, or in the woody descriptions by layers, cuttings, grafting, and budding; but in the annual tribe there is no other means than by sowing or setting the seed, except in some few sorts, by the planting of their cuttings, as in the chrysanthemeum, nauturtium, and some others; however, in a great number of kinds, where particular attention has conantly been bestowed in sowing the seeds from only the most perfect, they will continue tolerably permanent, and frequently come again the same, or with but very little variation.

In many sorts of plants of the kitchen-garden and annual flower kind, though there be a number of varieties in each, yet by good care, and constantly sowing seed from the most perfect plants, which wfe no signs of degenerating, they remain, year after year, permanent from seed.

But most of the perennial tribe, the herbaceous as well as the woody sorts, as being in general more variable from seed, afford great opportunities of continuing the permanency of any particular variety, by making use of the offsets from their roots, the suckers, layers, and cuttings, as well as by grafting and budding, as has been already seen.

It sometimes occurs, however, that plants, although not immediately raised from seed, will, on account of some accidental cause, vary materially from their usual natural growths, and assume quite different appearances, arising in conformance either of culture, climate, exposure, soil, age, diseases, abundance, or deficiency of nourishment, contusions, or other familiar circumstances; and by such means produce accidental varieties in some particular parts of their growth.

The aforesaid of the reality of the varieties is, in many sorts, readily and easily accomplished by a comparison of the variable plant with the specific definitions of the natural sort; and the variations of growth of the variety with the same parts in the natural plant. But still there are many varieties that require all the skill and knowledge of the most expert gardener to fully distinguish and ascertain them. It is, however, of material importance, in many cases of practical gardening, to have a nice and correct notion of the varieties of the plants which are to be cultivated, as the work can thereby be performed with greater certainty and advantage, as well as with more and better effects.

In the first volume of the Transactions of the Horticultural Society, T. A. Knight, esq., makes the following conclusions on the means of raising new and early varieties of fruits: after stating that "variation is the constant attendant on cultivation, both in the animal and vegetable world," and that "in each the offspring are constantly seen, in a greater or less degree, to inherit the character of the parents from which they spring," that as every particular sort of fruit acquires its greatest and perfect perfection in some peculiar sort of soil or situation, and under some similar mode of culture; the proper choice of such "must be the first object of the improver's pursuit; and that nothing should be neglected which can add to the fire, or improve the flavour of the fruit which it is intended to propagate. Due attention to these points will, it is contended, in almost all cases, he found to comprehend all that is necessary to infuse the introduction of new varieties of fruits, not equal merit with those from which they spring," but that, at the same time, the improver, who has to adapt his productions to the cold and unhealthy climate of this country, has still many difficulties to contend with; he has to com-
more often indebted to accident than to any plan of systematic culture; and contents himself with merely selecting and propagating from the plants of the earliest habits, which accident throws in his way, without inquiring from what causes those habits have arisen; and few efforts have been made to bring into existence better varieties of those fruits which are not generally propagated from seeds, and which, when so propagated, of necessity exercise during many years the patience of the cultivator, before he can hope to see the fruits of his labour, industry, and attention." The attempts which the writer has made to produce early varieties of fruit are, it is believed, all that have yet been made; and though the result of them is by no means sufficiently decisive to prove the truth of the hypothesis he is endeavouring to establish, or the eligibility of the practice he has adopted, it is amply sufficient to encourage future experiment on the subject.

It is noticed, that the frill fort of fruit which was subjected to experiment in this way, was the apple; some young trees of the desired varieties of which for propagation were trained to a fourth wall, until they afforded buds containing blossoms. The branches of which, then, in the following winter, were detached from the wall, and removed as great a distance from the wall as possible, in which place they continued till far advanced in their blossoms in the following spring, as to be in danger from frost. Then the branches were trained to the wall, where each blossom allowed to remain quickly expanded, and formed fruit, that in a few months attained perfect maturity; and the seeds produced plants that have ripened the fruit much earlier than other trees raised at the same time from seeds of the same fruit grown in the orchard. In this trial, the blossoms of each variety were fecundated by the farina of another kind; from which is supposed to have been attained in this as well as other similar instances a greater vigour and luxuriance of growth; but no earlier ripening of the fruits than in the plants grown by the ordinary modes of culture. The early maturity of those mentioned, is consequently ascribed to the other peculiarity of circumstances under which the fruit and seeds ripened from which they sprang.

By the same method of culture, several new varieties, that are the offspring afforded by the Siberian crab and the richest apples of this country, were obtained in the intention of providing fruits for the press that may ripen well in cold and exposed situations. The plants furnished in this manner poises a remarkable hardiness and luxuriance of growth, appearing in every way perfectly suited to answer the intended purpose. In each of these trials, some of the new varieties inherited the character of the male, and others of the female parent, in the greatest degree; and of some varieties of fruit, especially of the golden pippin, a better example was obtained by the introduction of the farina into the blossom of another apple, than by fowring their own seeds. The new variety of the Downton pippin, obtained in this manner from the farina of the golden pippin, will, if it be believed, be found, in a favourable season and situation, little if at all inferior to the golden pippin, when frill taken from the tree; but it is a good deal earlier, and probably cannot be preferred so long in a perfect state.

The next trials were on the grape, which, though less successful than the above in producing new varieties, were not less favourable to these conclusions. After fupposing a vineyard without fires in the winter, to afford a climate to the vine similar to that afforded by the southern parts of Siberia to the apple or crab-tree; the fame extensive variation of temperature taking place in it, and the sudden transition from great comparative cold to excessive heat, as productive of the fame rapid progress in the growth of the plants and the advancement of the fruit to maturity; he states that his first attempt was to combine the hardiness of the blossom of the black slufter, or Burgundy grape, with the large berry and early maturity of the true sweetwater, often confounded with the white chaffelas and white muscadine. In this case, the seedling plants produced fruit in his vinery at the age of three or four years, and in some of them it was very early; but the bunches were short and ill-formed, and the blossoms did not set by any means so well as he had expected.

On substituting the white chaffelas for the sweetwater, many varieties were obtained whose blossoms appeared perfectly hardy, and capable of setting well in the open air; and the fruit of some of them ripening a good deal earlier in the year than that of either of the parent plants. But the berries are smaller than those of the chaffelas, having less tender and delicate skins; and though not without much merit for the defect, they are generally better calculated for the press. In the latter intention, in a cold climate, it is supposed that one or two of these varieties will produce very great excellence. From the white chaffelas and sweetwater, plants have since been obtained, the appearance of which is greatly more promising; and the earliest variety of the grape which he has ever yet seen was produced from a seed of the sweetwater, and the farina of the red Frontignac. It is a very fine grape, resembling the Frontignac in colour and the form of the bunch; but it is feared that its blossoms will prove too tender to succeed in the open air in this country; a single bunch confining some berries is, however, all that has yet existed of this kind. Two new varieties of the vine, with striped fruit and variegated autumnal leaves, have also been produced from the white chaffelas and the farina of the Allipo vine: one of these has ripened extremely early, and is thought a good grape. As in all attempts to obtain new varieties of fruit, the propagator is at a loss to know the kinds which are best suited to answer his purpose, those varieties of the grape which he has employed with the most success are mentioned. In short, the facts which he has obtained on this subject, leave no doubt in his mind that varieties of the grape capable of ripening perfectly in our climate, when trained to a fourth wall, as well as of other fruits better suited to this climate than those which are now cultivated, may be readily produced; but whether the method of cultivation which he has adopted and advised be the most eligible, must be left to the decision of future and more extensive practice and experience.

Trials similar to these have been made on the peach; but it is stated that nothing more can yet be said of the result of them, than that the plants are perfectly healthy and luxuriant in their growth, affording sufficient evidence in their leaves of the good quality of the future fruit. And though he is uncertain at what age plants of this sort become capable of producing blossoms; the sudden changes in the character of the leaves and growth of thepeach ripened by him, which are now in their third year, lead him to believe that they will be in a state to produce fruit at the age of three or four years.

Upon the whole, from these and a close attention to the subject for years, it may be maintained that new varieties of every particular sort of fruit will in general be better obtained from the introduction of the farina of one variety of it into the blossoms of another, than by propagating from any single kind. Where trials of this nature are made between varieties of different size and character, the farina of the
VARIEITES.

the smaller kind should be introduced into the blossoms of
the larger, as under these circumstances it has generally,
though with some exceptions, been found that there is a
prevalence in the fruit of the character of the female parent,
probably on the following account. The seed-coats are
wholly generated by the female parent, and the regulate
the bulks of the lobes and plantula; and it has been noticed,
in raising new varieties of the peach, that when one stone
contained two seeds, the plants these afforded were inferior
to others. The largest seeds, procured from the finest
fruit, and from that which ripens most perfectly and most
early, should constantly be chosen. When it is intended to
propagate new varieties in this manner, it will be necessary
for the gardener to extract the f Stamina of the blossoms from
which he purpose to propagate some days before the farina
begins to shed. After young trees have risen from seed, a
certain time must elapse before they become capable of
bearing fruit, which, it is believed, cannot be shortened by
any means of cultivation. Pruning and transplanting are
equally hurtful; and no alteration in the character or
merits of the future fruit can be effected during this length
of time, either by manure or any fort of culture. The
young plants should be suffered to extend their branches in
every direction, in which they do not interfere with each
other in a hurtful manner; and the soil be just sufficiently
rich to promote a moderate degree of growth, without exci-
iting the plant to preternatural excretion, which constantly
brings on diseases. The foil of an old garden is par-
ticularly delusive in this way. The length of time that dif-
ferent sorts of fruit-trees require to attain the age of pu-
berty, admits of great variation. The pear demands from
twelve to eighteen years; the apple, from five to twelve
or thirteen; the plum and cherry, from four to five years;
the vine, three to four; and the rasperry, two years. The
strawberry, if its seeds be sown early, affords an abundant
crop in the following year; and he has produced several
new and excellent varieties of this fruit; but the hautboy
strawberry does not seem to propagate readily with the
other varieties, possibly belonging to an original distinct
sort. He has, however, obtained several off-spring from its
farina; but they have all afforded a feeble and abortive
blossom, and been of little value.

In another paper in the same volume, the same writer, in
speaking of raising new and early varieties of the potato,
says that those who have cultivated early varieties of this
plant, must have noticed that they never afford feeds or even
blossoms, and that the only mode of propagating them is by
the division of their tuberous roots. Alto farther, that
each variety has been found by experience, when long pro-
pagated, to gradually lose some of those good qualities
which it posseffed in the early stages of its culture; the
duration of a variety in the state of perfection, being limited
to about fourteen years. A good new variety of an early
potatoe is, of course, considered highly valuable by the
peron who raised it; and as such early varieties, according
to any method of culture heretofore practised, can only
be gained by chance from feeds of late kinds, they are not
very frequently produced. But by the method here de-
drected, feeds are readily obtained from the earliest and best
varieties; and the feeds of these may possibly, in successive
generations, finally afford much earlier and better varieties
than have yet appeared.

The cause of the constant failure of the early potatoe to
produce feed has been insufficient, and found "to be the pre-
ternaturally early formation of the tuberous root, which
draws off for its support that portion of sap, which in other
plants of the same sort affords nutriment to the blossoms
and feeds."

After taking several methods of placing the growing
plants so as readily to prevent this, he found the following
to be the best. He fixed strong flakes in the ground, and
raised the mould in a heap round the place of growth,
perfect contact with their bottom parts; and then planted
on their south sides the potatoes from which feeds were
defined. As soon as the young plants were about four
inches high, they were fastened to the flakes by means of
shreds and nails, and the mould washed away, by a strong
current of water, from the bases of their stems, so that the
fibrous roots only of the plants entered into the foil. As
the fibrous roots of this plant are perfectly distinct organs
from the runners, which give existence and subsequently
convey nutriment to the tuberous roots; and as the runners
spring from the stems only of the plants, which are, in this
mode of culture, placed wholly out of the foil, the formation
of tuberous roots is easily prevented. Whenever this is
therefore done, numerous blossoms will soon appear, and
almost every blossom will afford fruit and feeds. It is also
suggested as not improbable, that by introducing the farina
of the small and very early varieties into the blossoms of
those of larger sizes, and somewhat later habits, moderately
early varieties, adapted to field culture, and winter use, may
be obtained; the value of which to the farmer in the colder
parts of the kingdom, whose crops of this root are followed
by one of wheat, would be extremely great.

It is likewise stated by Mr. Biggs, in the above work,
that the different varieties of the apple-tree may be raised
in a ready manner by means of cuttings, and that the trees so
produced, "from healthy one-year old branches, with blo-
fom-buds upon them, will continue to go on bearing the very
finest possible fruit, in a small compass, for many years.
Such trees are also peculiarly proper for forcing, by way of
curiosity or luxury, and, it is believed, that they are
liable to canker when raised by grafting. This has
been more than once experienced in the golden pippin,
cuttings of which have remained seven years in perfect
health, when grafted, taken not only from the same tree, but
from the very branch, part of which was divided into cuttings,
cankered in two or three years. This mode of raising
young apple-trees was discovered by accident, from flitching
cuttings of these kinds of trees into the ground, as flower-
marks during a wet season, which took root.

In raising new varieties of carnations, much advantage has
lately been found from ripening the feed of the old plants by
means of placing them in the artificial heat or warmth of
some sort of houfe, frame, or other contrivance of these
kinds, as they naturally flower late in the season, and, of
course, fully ripe feed can seldom be procured in that way
for this purpose.

VARIETIES OF LAND, in Agriculture, the different sorts
or qualities of it, as they relate to the nature and manner of
its cultivation, or the uses to which it is applied. Though
no general principles are probably yet capable of being laid
down in regard to the comparative value or utility of dif-
ferent modes or plans of cultivation, or of the different
methods of proceeding in respect to crops that are laid re-
course to in different climates and situations, as the real nature
of it, and the particular circumstances to which it is
exposed and liable, in every instance, are not sufficiently
known; it is evident that all the less firm, clay, and cold
sorts of land are not so greatly benefited by much working
over, as those of the fluff and cohesive kinds, in which
more division of their parts and full aeration are essential

Vol. XXXVII. 

M necessary,
VARIGNON, Peter, in Biography, was born at Caen, in France, in 1564, and originally intended for the church; but imbibing an early taste for the mathematics, this kind of science became the object of his attention, in the profession of which he was discouraged by his relations, who obliged him to devote some part of his time to theology. With the abbé St. Pierre, who studied philosophy in the same college, he formed an intimacy; and they mutually encouraged and aided each other in their favourite studies. The abbé took him to his house, and in order to render him more independent, bestowed upon Varignon out of his own income, which was only 1500 livres a-year, 300. In 1686 the abbé took him to Paris, where he wholly employed himself in the study of mathematics, and where he formed an intimacy with Du Hamel, Du Verney, and De la Hire. From Du Verney he acquired a considerable knowledge of anatomy, whilst in return he taught him the application of mathematical reasoning to that subject. In 1687 Varignon became known by his "Projet d'une nouvelle Mécanique," dedicated to the Academy of Sciences. This treatise was much admired, and served to introduce him to two considerable places, viz. that of geometrician to the Academy of Sciences, and that of professor in the college of Mazarine. In 1690 he published "Nouvelles Conjectures sur la Pefanteur;" and he became one of the most early cultivators of the science of infinitesimals. Of his application and industry we have ample evidence in the volumes of the Academy of Sciences; his papers are numerous, and contain complete theories on the laws of motion, central forces, and the refraction of different media. In 1703 he suffered much from a severe illness, which impaired his naturally strong constitution, and reduced him for three years to a very languishing state. His physicians prohibited study, from which, however, he could not totally abstain. Having censured Dr. Wallis for asserting that there are certain spaces more than infinite, ascribed by this celebrated geometer to hyperbolas, whilst Varignon maintained that they were finite, his criticism was shewn to M. Carré, and by him caused to be printed in the Memoirs of the Academy, without his knowledge. After his recovery, he resumed his application, by republishing his "Projet d'une nouvelle Mécanique" in a new and enlarged form, by an extensive correspondence, and by reading lectures to his scholars in the college of Mazarine, as well as in the royal college, in each of which he occupied a professor's chair. In the latter part of his life, much as he valued peace, he was engaged in a scientific dispute with an Italian monk on the subject of tangents, and the angle of contact in curves. In the two last years of his life he laboured under an affectionate complaint, which baffled all remedies. At length, having finished his lecture at the Mazarine college, on the 22d of December 1722, he died suddenly on the following night. His character, says Fontenelle, was as simple as his superior understanding could require. He had no jealousy of the fame of others; for, indeed, he was at the head of the French mathematicians, and one of the first in Europe. In the discharge of every personal and social duty he was conscientiously strict. On the theory of the mathematicians, few mathematicians have laboured more successfully than Varignon; introducing into this science that mode of generalization which characterizes it, simplifying many of its principles, and resolving many questions that had not before been considered; such, especially, as relate to the doctrine of motion. His works, published separately, were "Projet d'une nouvelle Mécanique," 4to. Paris, 1687; "Des nouvelles Conjectures sur la Pefanteur," 12mo. 1692; "Nouvelle Mécanique," 2 tom. 1725; and his papers in the different volumes of the Academy of Sciences are very numerous. Montucla Hist. des Mathem. Fontenelle's Eloges des Academiciens.

VARILLIES, in Geography, a town of France, in the department of the Arribée; 10 miles W.S.W. of Mirepoix.

VARILLAS, Antony, in Biography, was born in 1624 at Gueret, in the Upper La Marche, and upon his settlement at Paris, Gaillon, duke of Orleans, made him his historiographer; and in 1653 he obtained a place in the royal library, very favourable for the prosecution of his historico-literary studies. Huet says of him, that no man ever brought to the illustration of French affairs so rich a provision of valuable observations, or so copious a store of domestic narrative. But he adds, that his excellent qualifications were disparaged by his immoderate assurance, which led him to confide in his own conjectures and speculations, and to relate with as bold acclamations things for which he had no authority, and which were altogether fictitious, as if he had been an eye-witness of them. In fact, Varillas was deficient of the most essential and estimable quality of an historian, a love of truth; and this has rendered his voluminous labours of inferior value. His leading object seems to have been the gratification and amusement of his readers. In the prosecution of this object he at first succeeded; his books were much read, and Colbert gave him a pension, which was afterwards withdrawn. In lieu of this, he contented himself with a pension which the French clergy granted him, as the reward of his services to the Catholic cause, obtained for his "Histoire des Revolutions arrivées en Europe en Matière de Religion," a mere party performance, concerning which Menage said to the author, "You have given a history of hereby fall of heretics." Bishop Burnet published a critique on part of it, which is said to have prevented Dryden from translating it; a task which was proposed to him, after his conversion to Popery, by James II. Bayle, and many others, have detected the errors and falsifications of Varillas. As his writings, which chiefly relate to French and Spanish history, are scarcely ever read or cited, it is needless to copy their titles. Varillas died in 1696, in easy circumstances, so that he left several legacies for pious purposes. Moreri. Huet. Nouv. Dict. Hlit. Gen. Biog.

VARINAS, in Geography, a province and city of South America, which in the year 1787 was detached from the government of Maracaibo, and made a separate government, constituted at the expence of those of Venezuela and Maracaibo. The chief has only the title of political governor, although his functions, in the district assigned to him, are the fame as those of other governors, in the civil, military, and religious
VAR

religious departments. He has also, like them, a galaey of 10000 dollars a-year. In order to secure its defence, a military was raised in 1803, and a garrison allotted to the city of Varinas, consisting of a company of 77 men. Varinas has been long known in the European markets, from the reputed quality of the tobacco which its territory produces; though it is in fact inferior to that which is raised elsewhere, particularly at Cumanacoa, in the province of Cuman. However, fugar, coffee, cotton, indigo, and in general all the fruits of the torrid zone, find here a soil adapted to each, and their quality is unrivalled. The commodities of this district are transported chiefly by water to Guiana; the shipping-place being five leagues below the city, at a spot called Tocunos. Within the jurisdiction of Varinas are also very large commons, furnishing a number of beves and mules, that are exported by the Oronoko, or confumed in the province. This city enjoys a tolerably pure air, and its inhabitants are reckoned at 6000. The public edifices consist of one parish church and an hospitol. It lies in N. lat. 7° 40', 100 leagues S.E. of Caracas.

VARIN-KEY, a small island in the Spanish Main. N. lat. 11° 10'. W. long. 83°.

VARIOLA, in Surgery, the small-pox. See INOCULATION and SMALL-POX.

V. VACCINA, the cow-pox, sometimes termed by modern medical writers vaccinia. See COW-POX and VACCINATION.

Eff. Ch. Receptacles cup-shaped, with a torn border from the crust, powdery, with a ferial disk beneath.

The whole of this genus was confounded by Linnaeus under his Lichen fagineus, and L. laetus, so far at least as its species were then noticed. They now amount, in the late work of Acharius, to ten, all of a crustaceous nature, found, some on the trunks of trees, others on rocks or walls, one on the ground. We have several, of British origin, to add to this list.

1. V. velata. Veiled Varioarla. Achar. n. 1. (Lichen velatus; Engl. Bot. t. 2062.) Parmelia velata; Turner. Tr. of Linn. Soc. v. 9. 143. t. 12. f. 11.—Crust limited, tarantaceous, thin, rugged, greyish, with a pale edge. Receptacles small, crowded; disk yellowish, veiled with a white membrane; border thick, even, of the substance of the crust.—Found by Mr. W. Borrer, but rarely, on the bark of afth-trees in Suffolk. The crust is thin, spreading in roundish patches, two or three inches broad, of a greenish-grey, corrugated in the disk, minutely fibrous at the edge. Receptacles numerous, sfiglike, about a line in diameter, pale salmon-coloured, with a thick smooth border, from which a white membrane is drawn across the disk, so as entirely to conceal that part.

2. V. multipunctus. Many-dotted Varioarla. Turner. Tr. of Linn. Soc. v. 9. 137. t. 10. f. 1. Achar. n. 2. (Lichen multipunctus; Engl. Bot. t. 2064.)—Crust ash-coloured, warty, rugged, tarantaceous, thin, with a fibrous edge. Receptacles hemispherical, with a white, aggregate, powdery disk, and smooth, lobed border.—Found, not uncommonly, on the trunks of beeches in Suffolk, by Mr. W. Borrer.—Nearly akin to the last, but the crust is more of a grey hue, and less uneven, though becoming rugged and warty by age. It changes nearly to white in drying. Fructifications the size of the leaf, but essentially differing in the want of a separate membranous covering, and in having each receptacle marked with three or four depressions, making for many distinct disks, in one thick lobed border. The surface of these disks is white and powdery; their inside pale chefnut.

3. V. globulifera. Veficle-fruiting Variolare. Turn. Tr. of Linn. Soc. v. 9. 139. t. 10. f. 2. Achar. n. 3. Prodr. Fl. Grac. n. 2432. (Lichen globuliferus; Engi. Bot. t. 2008.)—Crust spreading, faintly bordered, rugged, greyish-tinged with white powdery warts. Receptacles spherical, close; at length burking, with a thin ragged border, and blackish disk.—This also was discovered by Mr. W. Borrer, growing on the trunks of beeches and oaks in Suffolk, but rarely. Dr. Sibthorp met with it in Greece. The crust agrees in appearance with the following, but the globular vesicles, of the size of small peas, scattered over the disk, and each lodging a blackish receptacle of seeds, are peculiar to the present species.

4. V. faginea. Common Bitter Variolare. Perf. in Uit. Annal. falc. 7. 24. Achar. Meth. 12. Prodr. Fl. Grac. n. 2433. (V. communis; Achar. n. 4. Liehen fagineus; Linn. Sp. Pl. 1608. Achar. Prodr. 27. Hoffm. Enum. 18. A. t. 2. f. 4.)—Crust cartilaginous, rugged, polished, greyish, bordered with brown. Receptacles prominent, hemispherical, measly, very white, with a pale, flattish, at length naked, disk.—Very common on the trunks of beech, fycamore, oak, &c. throughout Europe, from Sweden to Greece. The crust, in a perfect state is circular, grey or greenish when young, corrugated, but with a smooth polished surface, and circumscribed by a thin border, elegantly coloured with concentric shades of brown. Numerous, prominent, almost flaked, tubercular receptacles are scattered over the central part, which are very white, especially in wet weather; powdery and somewhat convex in their disks, with a clumpy indiffluent kind of border. By age these, like the crust, become of a dirty white. Mr. W. Borrer has first observed a very bitter tallow in this species, not immediately perceptible, but after a while very strong, disagreeable and permanent, like the flavour of the Cyclamen root. No other species of Variolare has been found to have this bitterness.

We know not by what accident the learned Acharius, generally so accurate, has transferred it to our data, to which it has therefore called attention. His specific characters are so similar that the two species leave no doubt of what he intends under each, though we do not presume to decide on all his synonyms. This being the case, we do not feel authorized to change the old Linnaean name, though we readily allow that Linnaeus here confounded two species.

5. V. diseoides. Flat-cupped Variolare. Perf. in Uit. Annal. falc. 7. 23. Achar. Meth. 14. (V. amara; Achar. n. 5. Lichen diseoides; Achar. Prodr. 28. Engi. Bot. t. 1714. L. fagineus; Hoffm. Enum. 19. B. C. t. 2. f. 4. 5. L. albeleans; HUDF. 529. L. caespitosa; Light. 807. Lichenoides candidum et farinaceum, tentella ferre plania; Dill. Mufc. 131. t. 18. f. 11.)—Crust cartilaginous, cracked, somewhat rugged, polished, greyish, bordered with brown; at length powdery. Receptacles flatish, measly, very white; at length concave, deprefled, with a dilated torn border.—This is probably as common as the preceding, with which it has been confounded. The chief mark of distinction consists in the little elevation of its receptacle, which, after discharging their powdery contents, become quite concave, with a thin expanded margin. Hence the present plant has been separated by several botanists from faginea, even without their advertizing to its infidelity, remarked by Mr. W. Borrer.
VARIOLITE, in Mineralogy, a name given by some mineralogists to porphyritic rocks, in which the imbedded sublimes
VAR

substances are imperfectly crystallized, or are rounded, giving the hone a spotted appearance.

VARIOREM, in Matters of Literature, a term or phrase of abbreviation, and for an edication of a clastic author, printed in Holland, with the notes of divers authors upon it: Cum notis variorum, or cum selectis variorum observationibus.

In this fenfe we say, Plautus variorum; a set of Dutch variorum, &c. Many of the variorum are valuable editions.

The word is the genitive plural of the Latin varius, different, divers.

VARIS, in Ancient Geography, a place of the isle of Albion, on the route from Segontium (Caerarnon) to Deva (Chelter), between Conovium (Caer-Rhydn) and Deva; supposed to be Bodvury; 32 miles from Deva, or Chelter.

VARIVS, in Ichthyology, a name used by most authors for a small fresh-water fish, common in brooks and running waters, and well known in England by the name of the minnow.

VARIVS Mus, in the old authors of Zology, a name used for the fame creature they otherwise called mus ponticus; which seems to have been no other than the European flying squirrel.

VARIX, from varius, irregular, in Surgery, denotes an uneven swelling of a dilated vein. The tumour is soft, generally not painful, and presents an appearance as if fludled with several knobs, or tubercles, which correspond to the valves in number and situation. The diseased vein is also elongated as well as dilated, and describes in its course a variety of windings or convolutions. A particular account of the symptoms, causes, and treatment of this common disease, will be found under the head of Varicoso Fina.

VARIX, in Animals, a sort of puffy dilatation or enlargement in some part of a vein, forming a kind of knot. It mostly happens in the veins of the legs, and is of the nature of spavin. It may readily be removed, on its tiff appearance, by the use of cold solutions, and applications of that sort, frequently applied, and suitable bandages.

VALER, in Geography, a town of Germany, in the bishopric of Munster; 4 miles N.N.W. of Coesfeld.

VALLET. See VALET.

VARMAT, in Geography, a town of Hungary; 12 miles N.N.W. of Zatmar.

VARO, a river of Italy, which runs into the Taja-mento, 2 miles N. of Latifiana, in the country of Friuli.

VARNA, in Ancient Geography, a town of Asia, in the interior of Media. Ptolomy.

VARNA, in Geography, a sea-port town of European Turkey, in Bulgaria, situate on a gulf or bay of the Black sea, to which it gives name, at the mouth of the river Varna; the fee of a Greek archbishop. In the year 1443, Ladislaus, king of Hungary, was defeated and slain by Amurath I. emperor of the Turks, near this town; 144 miles N. of Conflantinople. N. lat. 43° 14'. E. long. 27° 10'.

VARNA. See VRAN.

VARNAV, a mountain of Greece, near Athens.

VARNAVIN, a town of Ruflia, in the government of Kollrom, on the Vetelga. N. lat. 57° 10'. E. long. 45° 14'.

VARNI, in Ancient Geography, a people of Asia, in Bacstria. Ptolomy.

VARNISH, or VERNISH, Vernix, a thick, viscous, glossy liquor, used by painters, gilders, and various other artificers, to give a gloss and luster to their works, as also to defend them from the weather, dust, &c.

There are divers kinds of varnishes; some of the principal of which are as follow:

VARNISH, Amber, is prepared in the following manner: Put four ounces of amber into a crucible, and melt it with a small degree of heat, and pour it out upon an iron plate; when cool, reduce it to powder, and add to it two ounces of drying oil, that is, linseed oil thickened by boiling it up with lighthouse, and one pint of oil of turpentine, and diffuse the whole together into a liquid varnish.

This simple amber varnish is of great use for many purposes, and is said to be the basis of the fine varnishes which we see on coaches, and may be prepared without drying oil, by boiling the powder of amber in linseed oil, or in a mixture of linseed oil and oil of turpentine. Drying oil is commonly used by the workmen; but Dr. Lewis thinks it more eligible to take the oil unprepared, that the boiling requisite for giving it the drying quality may be employed at the same time in making it act upon the amber. It has generally been thought, that amber will not at all diffuse in oils, till it has suffered a degree of decomposition by fire. But Hoffmann relates an experiment, in his Observations Physico-Chemical, which discovers the solubility of this concrete in its natural state. Powdered amber, with twice its quantity of oil, was put into a wide-mouthed glass; and a digestor, or strong copper vessel, being filled about one-third with water, the glass was placed in it, the cover of the digestor wereed down tight, and a moderate fire continued an hour or more: when cold, the amber was found dissolved into a gelatinous, transparent mass. In Dr. Stockar’s Specimen Inaugurale de Succino, printed at Leyden in 1760, we have an account of other experiments made by himself, in conjunction with M. Ziegler of Winterthur; from which we learn, that by continuing a simmering heat twelve hours, and coning the vapour as much as it returns vessels would bear without bursting, (the danger of which was avoided by making a small notch in the cork-stoppers,) powdered amber dissolved perfectly in expressed oils, in turpentine, and in balm of copaiba: a strong copper vessel, with a cover screwed on it, seems most eligible; and for the greater security, a vessel may be made in the cover, kept down by a spring, that shall give way before the confined vapour is of sufficient force to endanger bursting the vessel. Moreover, by digestion for a week in clove-stopped glass vessels, in which the compresse could not be very great, solutions equally perfect were obtained. The solution in rape-seed oil, in oil of almonds, was of a fine yellowish colour; in linseed oil, gold-coloured; in oil of poppy-seeds, yellowish-red; in oil olive, of a beautiful red; in oil of nuts, deeper coloured; and in oil of bays, of a purple-red. The solutions made with one third, and with balm of copaiba, were of a deep red colour, and on cooling, hardened into a brittle mass of the same colour. All the solutions mingled perfectly well with spirit of turpentine. Those made with the oils of linseed, bays, poppy-seeds, and nuts, and with balm of copaiba and turpentine, being diluted with four times their quantity of spirit of turpentine, formed hard, tenacious, glossy varnishes, which dried sufficiently quick, and appeared greatly preferable to those made in the common manner from melted amber.

An amber varnish may also be made by boiling down some colophony, or turpentine, till it becomes black and friable, and mixing this in a glazed earthen vessel, sprinkling in, by degrees, twice as much amber in fine powder, with the addition of a little spirit or oil of turpentine now and then. When the amber is melted, sprinkle in the same quantity of linseed oil, continuing to mix them, and to add more spirit of turpentine, till the whole becomes fluid; then strain out the clear
clear through a coarse hair bag, pressing it gently between hot boards. This varnish, mixed with ivory-black in fine powder, is applied, in a hot room, on the dried paper paste of which the pâAPER mâché is made; which is then set in a gently heated oven, next day in a hotter oven, and the third day in a very hot one, and let stand each time till the oven is grown cold. The paste thus varnished is hard, durable, glossy, and bears liquors hot or cold. Lewis's Com. Phil. Techn. p. 367.

An amber varnish may be otherwise made by melting eight ounces of Chio turpentine, and when fluid, pouring into it, by degrees, a pound of fine powdered amber, and flurring it; and when it is properly mixed, setting it on fire for half an hour, taking it off, and flurring it well, and adding to it two ounces of the white colophony. It is again to be put on a brisk fire, and covered clothe; when the mass is perfectly fluid, and taken off to cool, a pound of linseed or poppy oil, made drying, is to be poured in boiling hot, and flurred till it be incorporated with the mass; and then a quart of hot turpentine is to be added, and the whole well flurred. Let it then cool, and strain it off for use; when, if it has been properly made, it will be quite clear. See GILDING on ENAMEL AND GLASS.

VARNISH. Black, for japanning on wood or leather, is prepared by mixing lamp-black or ivory-black with a proper quantity of a strong solution of gum lac in spirit of wine. (See JAPANNING.) The lamp-black is commonly preferred to the ivory-black, on account of its uniting better with the fluid, and working smoother. The thicker part of the varnish, which settles at the bottom, is used with the lamp-black for the first coatings, and the mixture applied at different times, in a hot room, one layer after another, is dry, till a full body of colour is obtained; after which, the piece is wafted over in the same manner several times, with the finer part of the varnish, just tinged with the lamp-black, so as to make a coating of sufficient thickness to bear polishing with tripoli. Iron fruit-boxes, mourning buckles, &c. are coloured black, by making them considerably hot, and applying on them in this flate a thick mixture of lamp-black, with a certain varnish called gold-size, consisting of the drying oil, turpentine, and the pigment called Naples yellow; but the yellow might be omitted, and the varnish formed at once by mixing lamp-black with a proper quantity of turpentine and drying oil. The workmen, as Dr. Lewis says, frequently employ, as varnish for metals, a mixture of lamp-black, with the fuscumings, &c. of different oil paints; the mixture is applied with a pencil, and the piece afterwards baked in an oven with a heat somewhat greater than is used for the pâAPER mâché. Naples yellow, a superfine ingredient in the black varnish, is the basis of the dark-brown which we see on some iron fruit-boxes; this pigment changing to a brown in baking with the varnish. Lewis. See LACQUER.

The excellent black varnish of China and Japan, which has been hitherto imperfectly imitated in Europe, and which was formerly thought not to be a natural composition of resins, being coloured with black pigments, has been discovered by the later travellers into those countries, to be a native juice, exuding from incisions made in the trunks of certain trees. Mr. Miller, in consequence of a letter from the abbé Mazeas to Dr. Hales, containing a communication of the discovery of a plant by the abbé de Sauvages, which he calls toxicoDNDRON CAROLINIANUM folius pinnatis, florisbus minimis berbaceis, and the black juice of which adheres, without the leaf acrimony, to cloth with more force than any other known preparation, took occasion to shew, that this American toxicoDNDRON is the famous species of plant from which the inhabitants of Japan procure the varnish with which they stain all their utensils; adding, that the Calicutans are also painted with the juice of this shrub. This American toxicoDNDRON (see POISON-TREE) is the same plant, as he affirms, which is mentioned by Kämpfer, in his Amoenitates Exoticae, by the title of arbor varnicifera legitima, folio pinnato juglandi, frutu rosanofo ciceris fuscis; i.e. the true varnish-tree, with a walnut-tree leaf, and a branching fruit like cicers. It is called by the inhabitants of Japan frize, or leftza-dajx, and also ura, or ura-na. Kämpfer has also described the wild or spurious varnish-tree, called fajf-no-ki by the natives, which he says agrees with the other in every part, except that the leaves of the trunks are narrower; but Mr. Miller is of opinion that this is a different species, if not of a different genus, from the true varf; and says, that the varnish yielded by it is of little effect. The account which the Jesuits at China have given of the manner in which the varnish is procured, is as follows: they first cut the back of the branches of the shrub, in different places, with a knife; and thus there flows out a white clammy juice, which is received into wooden vessels; and when these become dry, they tap the stems of the shrubs near the roots, so that all the juice is drawn out of them. The shrubs are then cut down to the ground, and from their roots new stems arise, which in three years will be fit for tapping. The juice turns black when exposed to the air; it heats without turning four; but being of a poisonous nature, it is dangerous to handle it. This native varnish wants hardly any preparation; but if any dirt should happen to mix with it, it is cleaned by being strained through coarse gauze, put into wooden vessels, and covered with an oil called ioj, and a skin, in order to prevent its evaporating. In this state it is carried over to China and Japan for sale. The shrub is chiefly cultivated in the provinces of Tф-kooko and Tф-kooko, and the best varnish, according to Kämpfer's account, is produced about the city Jaffino; but there is an ordinary sort of varnish, called nam-rai, brought from Siam, which is collected in the province of Corfama, and in the kingdom of Cambodia, from the tree anacardus, called by the inhabitants tong, or tu-ra, the fruit of which is called in our shops anacardium. To collect this liquor, they bore a hole in the trunk, and insert a tube. By this method they procure as much of it as is sufficient, not only to varnish all the utensils of China, Tonquin, and Japan, but it is even exported in close wooden vessels to Batavia, and other parts of India. This varnish, says Kämpfer, is not only fold quite pure, but likewise coloured, with Chinese native cinnamon, and a kind of red earth, which the Dutch formerly, but now the Chinese bring them, and also with the materials of which they make their common Japan ink. Mr. Ellis has controverted the opinion of Mr. Miller, and endeavoured to shew that the American toxicoDNDRON is not the same with Kämpfer's arbor varnicifera legitima; alleging, that Kämpfer's description of the true varnish-tree does not agree with this toxicoDNDRON; and he inclines to the opinion, that the Carolina pinated toxicoDNDRON, or poifon-an, is the same with the fajf-no-ki, or spurious varnish-tree of Kämpfer. Mr. Ellis also thinks it is not improbable, that the varnish mentioned by Kämpfer, as obtained from the oriental anacardium, is the same with that mentioned by father d'Incarville, in the Phil. Trans. vol. xlvi. p. 254, called tong-yew; which is so universally used in China for preferring and ornamenting their furniture. See this controversy between Mr. Miller and Mr. Ellis at large, in Phil. Trans. vol. xliv. part i. p. 157—166. part ii. p. 806—876. vol. i. p. 430—456. See POISON-TREE, LINEN, and JAPANNING.

VARNISH. BROWN, for Metals. See Black VARNISH, supra.

VARNISH,
VARNISH.

Varnish, Copal Oil, called in France varnish marins, is made by pouring into a well-glazed strong earthen pot, in shape resembling a chocolate pot, and in size large enough to hold about a gallon, and made warm, four ounces of Chio or Cyprus turpentine, and when this is diffused, eight ounces of finely powdered amber; mingling them well, and setting them on the fire for a quarter of an hour; take off the pot, and pour gently into it a pound of copal, finely bruised, but not powdered; stir the mass, and add four ounces of Chio turpentine, and a gill of warm turpentine oil; then let it on a brisk fire for about half an hour, and taking it off, stir the contents well, and add two ounces of the finest and whitest colophony. Let the pot be put on a very brisk fire, and remain till the whole is diffused, and become as fluid as water; let it be removed from the fire, and remain for a few minutes, and then gradually pour in twenty-four ounces of poppy, nut, or linseed-oil, made drying, and boiling hot, and stir the mass with a deal flack. When the gums and oil are thoroughly incorporated, set them over the fire for a few minutes, Still stirring them about, and let them boil once up; and having taken off the pot, pour into it a quart of hot turpentine; stir them together, and give them one boil up; take off the pot, and pour into it a pint more of hot turpentine, Still stirring it well. If the gums are thoroughly melted, and well incorporated, the varnish is made; which, being cool, is strained through a close cloth into another vessel, and, if it be too thick, thinned with oil of turpentine, till it becomes of the consistence of linseed-oil; strain it a second time, bottle it for use, and let it stand a month, at least, before it is used. This varnish is used for coaches, cabinets, &c.; and the piece, whatever it be, after having been varnished smoothly, and dried in the intervals half a dozen times, and suffered thoroughly to dry, must be rubbed with a wet coarse rag, dipped in pumice-Flone, powdered and sifted, till the streaks of the brash and all blemishes are removed. When it is perfectly smoothed, washed, and dried, the coats of varnish are to be repeated, for ten or twelve times, till there be a sufficient body. After having again used the powdered pumice-flone, and washed it off as before, let it be rubbed with fine enery, till the surface becomes even and smooth as glass; then with powder of fine rotten Flone, till by palting the palm of the hand two or three times over the same place, you discover a gloss equal to that of glass: having dried it clean, dip a rag, or piece of flannel, in sweet oil, and rub the surface a few times over, and clear it off with fine dry powder, flour, or the hand; and a piece of fine flannel, dipped in flour, and rubbed over it, when cleared of the oil, will give it an excellent lustre. Between every coat of varnish it will be advisable, if the subject admits of it, to let it in a warm oven; or to heat the varnished pieces by roves. See COPAL.

Varnish, Gold-coloured. See LACQUER.

The composition of a gold-coloured varnish, used by the English artists for brash and silver, was communicated to some of the French academicians in 1720, by Mr. Scarlet, and in 1735 by Mr. Graham, and published in the volume of the French Memoirs for 1761. It is as follows: Take two ounces of gum lac, two ounces of yellow amber, forty grains of dragon's blood in tears, half a drachm of saffron, and forty ounces of good spirit of wine: infuse and digest in the usual manner, and then strain through a linen cloth. The piece to be varnished must be heated before the liquid is applied: it receives from the varnish a gold colour, and may be cleared, when fullled, with warm water.

Varnish for preserving polished Iron from Rust. See IRON.

Many methods have been used for preserving iron utensils from rust, as animal fats, oils, boiled oil mixed with melted lead, &c. Homberg's salve for this purpose consists of two pounds of hog's-lard, an ounce of camphor, and as much black lead as will render the mixture of an iron-colour; when this is used, the iron must be previously heated. M. Reaumur has discovered a better composition for this purpose: it is oil, infiltrated by being exposed to the air in flat shallow vessels, so as just to cover the bottom, mixed with a solution of copal in spirit of wine: this forms an elegant hard varnish, which, rubbed on polished iron, made a little hotter than the hand can bear, will cover it with a solid, thin, transparent coat, without any injury to its colour or appearance. See RUST.

Varnish, Laca, is made of gum laca and spirit of wine, frequently shaken till the gum be dissolved, then strained, and the clear liquor decanted off. The laca ought to be of the kind called seed laca. (See LAC.) Three ounces of this, well purified by repeated ablation of water, dried and powdered grofely, should be put into a bottle with a pint of rectified spirit of wine, so as to fill about two-thirds of it, and the bottle placed in a gentle heat; proceeding as above: though for varnishing ordinary woods, shell laca is often used. For this purpose, five ounces of the best shell laca should be grofely powdered, and put into a bottle, holding about three pints or two quarts, with one quart of rectified spirit of wine; and placed in a gentle heat: the mixture must be filtered through a flannel bag. To this varnish, the colours used in varnish painting may be added, and properly diluted with rectified spirit, and kept in phials, or tin vessels closely stopped for use. But this will not stand against the weather.

For various preparations of this kind, see JAPANNING and LACQUER.

Varnish, Maltich, is made by putting five ounces of powdered maltich into a proper bottle, with a pound of spirit of turpentine, and letting them to boil in balneo Marit, till the maltich be diffused, and straining the solution through flannel. This varnish may be converted into a proper varnish for painting, by grinding one ounce of gum anime on a flone with water, till it becomes an impalpable powder; then drying it, and grinding it again with half an ounce of turpentine, and afterwards with the proper colours, and moistening it with the maltich varnish, till the mixture be of a due consistence for working with the pencil. It must then be kept in phials or tin vessels, and diluted, as there may be occasion, with spirit of turpentine.

Varnish for preserving Paintings. See PICTURE.

For this purpose some have recommended the following composition: viz. half a pound of gum fandarac; an ounce and a half of Venice turpentine; three-quarters of an ounce of each of the gums anime and copal; half an ounce of maltich; benzoin, gum elemi, and white resins, each two drachms, and one pound of rectified spirit. The benzoin and gum anime powdered, are put with the Venice turpentine into a phial, with eight ounces of the spirit of wine: the copal and resin powdered are also put in a phial with six ounces, and the powdered gum elemi, with two ounces of spirit of wine. The several phials are frequently shaken, till the gum, &c. are dissolved; then the solutions are strained through a fine linen in our bottle, and when the mixture has stood some days, it is decanted off clear, and kept in a separate bottle for use. Some have substituted the farcocola for the copal. Another composition is formed, by dissolving maltich and fandarac, grofsly powdered,
VARNISH, White, is usually made of gum sandarac and gum mastic, diffolved in spirits, left to settle two days, then strained through a linen cloth, and, after standing some time, the clear poured off, and bottled for use.

The more curious artists diffuse the two gums separately; and having made a separate varnish of each, mix them occasionally, as their work requires a stiffer or a softer varnish.

But for the left white varnish more gums are required; viz. Venice turpentine, gum copal, elemi, benzoin, anime, and white resin.

Befides these, there are hard and soft varnishes, or grounds, used by the etchers and engravers. See Engravers' Varnish, which is also used for a kind of glossy coat, with which potter's-ware, Delfe-ware, China-ware, &c. are covered, to give them a smoothness and lustre. Some preparation of lead is the varnish ordinarily used for the first; and earths for the second. See GLAZING and POTTERY.

The true varnish used by the Chinefe and Japanefe, to give that inimitable lustre to their porcelain, is one of the grand secrets in that manufacture; and is one of the great things wanting, to make Delf and French ware vie with the Chinefe. Several have described the preparation of it, particularly Kircher; but none ever succeeded in the trial. See Porcelain and Varnish, supra.

VARNISH is also a term applied to the colours which antique medals acquire in the earth.

The value of a medal is heightened by a beauty, nature alone was able to give, and art has never yet attained to counterfeit: we mean the colour or varnish with which certain foils tinge the medal; some with a blue, almost as beautiful as that of a turcois; others with an inimitable vermilion colour; and others with a glossy shining brown, infinitely beyond any of our figures in bronze.

The most usual varnish, however, is a fine green, which hangs to the most delicate strokes without effacing them; much more accurately than the finest enamel does on metals. Brass alone is susceptible of it; for as to silver, the green rust that gathers on it, always spoils it; and it must be scour'd off with vinegar, or lemon juice.

There is also a false or modern varnish; which the falfiers of medals give to their counterfeits, to give them the air of antiquity: it is discovered by its being softer than the natural varnish, which is as hard as the metal itself.

Some lay their spurious medals under ground, where they contract the degree of varnish, that they impose on the less knowing: others use sal ammoniac, mixed with vinegar; others the acid spirit of nitre, &c.

VARODOPA, or VERODOPA, in Ancient Geography, a province in the environs of Macedonia, according to Eutropius. Ortelius makes it a country of Thrace, writing it Rodopa.

VAROE, in Geography. See VARIO.

VAROLO, Costanzo, in Biography, was born at Bologna in 1542, and became a professor of phyfic and surgery in his native city. In 1572 he was invited by pope Gregory XIII. to settle at Rome as his first physician, and professor in the college of Sapienza. He was advancing in reputation by his anatomical discoveries, as well as in his practice of medicine and surgery, when a premature death cut him off in his 53d year of his age. He was particularly distinguished in the anatomy of the brain, which he described in his work "De Nervis Opticis nonnullis aliis prae coetu communes Opinionem in Humano Capite observavit Epifola ad Hieronymum Mercuriale," Patav. 1570. Among the parts of the brain which he discovered, or more accurately described, was that known by his name, the "Pons Varoli," formed by the union of the crura cerebri and cerebelli, and the place whence several nerves originate. After his death was published "De Resolutione Corporis Humani," a work which is a compendium of anatomy, chiefly according to the ancients, but with several new observations by himself. Haller. Eloy.

VAROLO Pons, in Anatomy. See Pons.

VARORE, in Geography, a town of Hindoostan, in Daramaul; 14 miles N. W. of Darcumpoor.

VAROTARIO, Dario, in Biography. See Paduano.

VARPA, in Geography, an island near the N. E. coast of Sumatra, about 50 miles in circumference. S. lat. 2°. E. long. 100° 29'.

VARRO, Marcus Terentius, in Biography, the most learned of the ancient Romans, received from Pompey the Great, in the piratical war, a naval crown, and joined this chief in the civil war against Caesar; but afterwards submitting to the latter, he was employed by him in making a collection of books for the public library which he proposed to establish at Rome. The death of Caesar prevented the accomplishment of this design; and Varro, being involved in the proscription by the triumvirates, escaped with his life, but with the loss of his library. After the restoration of tranquillity, he retired for the prosecution of his studies, and composed books till his 88th year. His life was prolonged to the age of 90, and he died about the year B. C. 27. He is highly extolled for his various talents and literary performances by ancient writers, and particularly Cicero in his "Academics." Aulus Gellius cites a pasage from Varro, in which he declares of himself, that to the 70th year of his life he had composed 490 books, and he continued to write to his 90th year. The subjects on which he wrote were grammar, eloquence, poetry, the drama, history, antiquities, philosophy, politics, agriculture, nautical affairs, architecture, and religion. He was also the first Latin author of that species of satire called the Menippian, from Menippus, a Greek, its inventor, which was written in prose, with a mixture of verse in different measures. (See Menipean.)
VAR

Menippus.) Such and so pre-eminent was the reputation of Varro, that when Aemilius Pollus, in the reign of Augustus, opened the first public library at Rome, and placed in it the effigies of various learned personages, he was the only living writer who had the honour of this distinction. The only relics of his numerous works are six books, in an imperfect state, out of twenty-four, which he composed on the Latin language, with three books on agriculture, and a few fragments of his satires and epigrams. The former are printed among the "Auctores de Lingua Latina," and the latter among the "Auctores de Re Rutilica."

Gen. Ch. Cat. Perianth of one leaf, inferior, tubular, with five long, slender, recurved teeth, permanent. Cor. of one petal, tubular, tube cylindrical; limb in five deep spreading segments. Stam. Filaments five, awl-shaped, the length of the corolla, inserted into its tube; anthers oblong, incumbent. Fil. Germen superior, ovate; style long, the length of the corolla; stigma four, bristled-shaped. Peric. Drupa ovate, of one cell, inclosed in the swelling calyx, but not connected with it. Seed. Nut roundish, of four cells. Eff. Ch. Corolla five-cleft. Calyx tubular. Drupa superior, covered with the permanent calyx. Nut of four cells.

A West Indian genus of shrubby plants, with simple, alternate, rarely almost opposite, rough leaves; and terminal, aggregate, rather ornamental, flowers. They are little known in our flves, nor has any one species as yet been exhibited in our popular periodical works. Varroonias are next akin to Tournefortia (see that article) but the leaves deeply divided calyx, and four slender filaments, are sufficient to mark the present genus, without advertising to their fruits, which are not in all cases well understood.

1. V. lineata. Round-skiped Varroonia. Linn. Sp. Pl. 275. Willd. n. 1. Ait. n. 1. Swartz Obs. 87. (V. fruticosa, foliis rugosis, ovatis, subhirsutis, ferratis, alternis, capitulis subrotundis; Browne Jam. 172. t. 13. f. 2. V. humilis; Jacq. Amer. 41. Ulmi anguillofoci facie Baccifera jamacenseis, foliis supemae fiscbris subifinis villosis, floribus flavis perupulillos, frustra botryoide monopofero; Pluk. Almarg. 395. Phyt. t. 328. f. 57.)—Leaves lanceolate, minutely hairy, marked with brown depressed veins. Flower-flakes mostly axillary, combined with the fruit-flakes. Spikes globose.—Common in the lower woody lands of Jamaica. The flow is three or four feet high, with many slender, round, downy, crooked, entangled, leafy branches. Leaves spreading, or rather dependent, two inches long, taper-pointed, dilately and irregularly serrated; roughish, like a very fine file, with minute rigid hairs above; densely downy and hoary beneath. Fruit-flakes hairy, a quarter of an inch long, united for half their length, to the base of each simple, solitary, downy flower-flake, which is about half the length of the leaf, and bears a round head of small whitish or yellowish flowers. Pluckeius's figure is a much better representation of the Linnaean specimen from Browne himself, than his own plate, particularly with respect to the situation of the flowers. We cannot but suspect some error, and that the said plate may represent a species not hitherto well defined.

2. V. bullata. Blistered Varroonia. Linn. Sp. Pl. 275, excluding Jacquin's syonym. Am. Acad. v. 5. 394. Willd. n. 2. Swartz Obs. 88.—Leaves ovate, veiny, rugose, rough with callous tubercles and bristles. Spikes globose, on long rough flake, from the forks of the Rem.—Native of Jamaica. The Linnaean specimen is from Browne, but does not answer to the description of either of his species. The branches are forked, extremely rough with minute warts, and rigid ascending bristles, as are likewise the fruit-flakes and flower-flakes. Leaves an inch and a half or two inches long, about four times the length of their flake, nearly elliptical, acute, ferrated, reticulated with copious veins, and minutely blistered in the interstices; besprinkled on the upper side with callous tubercles and bristles, which turn white by age, when the leaf becomes tawny; paler, with hairy veins, beneath. Flower-flakes from the forks of the branches, solitary, from one inch to two inches and a half long, erect, simple, very rough, quadrangular upwards. Spike globose, of fix or eight flowers. Calyx corrugated, bristly, with linear recurved teeth. Corolla not much longer than the tube of the calyx, with five plats in the limb. Fruit tuberculated. Many doubts have arisen respecting this species. What we have here, with all possible precision, defined, is certainly the Linnaean authentic specimen, which we should suspect to be the Lantana Radula of Swartz. Ind. Occ. 1557. Willd. Sp. Pl. v. 3. 317, to judge by the description, not having seen the plant. Nevertheless our's has the calyx and corolla of a Varroonia, and the habitat of the plant is so near V. mirabilis, as figured by Jacquin, that Linnaeus may well be excused for supposing them one and the same. In the Linnaean herbarium are two other specimens, sent by Rollander, and marked likewise V. bullata. It must be to thefe that Swartz alludes, when he says, in his Obs. 88, "there is a specimen of V. globosa in Herb. Linna. under the name of bullata." Whether this be correct or not, there have never been described as bulbata, though, by mistake, so named.

3. V. mirabilis. Salver-flowered Varroonia. Jacq. Amer. 41. t. 33. Willd. n. 3. Ait. n. 2. Swartz Ind. Occ. 465.—Leaves ovate, rough, ferrated. Spikes roundish, unequal. Caly whole-shepia; its tube three the length of the calyx. Native of Hisafpanches, even in hedges near the town of Pecan-Prince. Jacuim. The most elegant of its genus, often twelve feet high. Leaves two inches long, rough on both sides. Flower-flakes lateral and terminal, measuring three or four inches, and bearing each a simple or divided round-headed flower, of numerous white insodorous flowers, very handfome, the size of Maynia of Peru. Segments of the calyx fmall, ovate, ending in long bristles. Drupa red, the size of a pea, full of sweet nutritious pulp. Nut depressed. Such is the plant of Jacquin, and we must suppose Swartz's the fame, in spite of some slight incongruities of description. We have never seen either.

4. V. martius-carra. Marionia Varroonia. Jacq. Amer. 41. t. 32. Willd. n. 4. Ait. n. 3.—Leaves ovate, pinnated. Spikes oblong, dent. Calyx-teeth linear, half the length of
of the tube.—Native of Martinico. Sent to Kew by sir Joseph Banks, in 1795. It is said to flower in the hove about August and September.—*A. flava* as tall as a man; the young branches only roughish with close-prehended hairs. *Leaves* three inches long, sharply serrated; rough above, with minute deflected hairs; soft and downy at the back. *Flower-flax* solitary, a little above each fork of the branch, silky, an inch and a half long, each bearing a deuce *spike*, about an inch long, of many funnel-shaped, probably white, flowers. *Calyx* silky, with broader and shorter teeth than any of the foregoing.

5. *V. globosa*. Globose Varroia. Linn. Sp. Pl. 276. Wildd. n. 5. Jacq. Amer. 41. —"Leaves lanceolate-oblong. Stem forked. Flower-flaxes axillary, elongated, naked. Spikes globose.—Native of the West Indies. An oblong species, of which we can give only the Linnaean specific character, the author of which adds *pellicibus et dichotomatis nudis*; meaning, probably, that whenever a split springs from the fork of the flower, it is unaccompanied by a leaf. Linnaeus further says, that the calyx-teeth are long, linear, and recurved. Whether the specimen above-mentioned from Rolander (see n. 2) has been the same is not known. Sir Joseph Banks has favoured us with what he considers as *V. globosa*, from Von Rohr, which may be the same; the leaves and flower-heads are much blunter, but hardly enough to make a specific distinction.

In this the leaves are scarcely above an inch long, rough and rather hairy, especially beneath, as are also the branches and flower-flax. *Flowers* numerous, in dense, globular, silky, flattened heads, either from the forks of the younger branches, or each opposite to a leaf. *Calyx-teeth* as described by Linnaeus.

6. *V. curassavica*. Long-spiked Varroia. Linn. Sp. Pl. 276. Wildd. n. 6. Jacq. Amer. 42. n. 7. Swartz Obs. 88. (V. alligures farinumosa, folium et capitulis oblongis; Browne Jan. 172?)—Leaves elliptic-oblong, minutely toothed. Spikes oblong. Calyx-teeth triangular, slightly pointed.—Sent by Von Rohr from the West Indies, and given us by the late Mr. Dryander, as the authentic plant of Jacquin, compared double-flus with his specimen. Yet the calyx-teeth have less evident points than he describes, and the flower is rather large. Whatever our friend Mr. Swartz may have had for *V. curassavica*, we can assert that our's is certainly distinct from *marticenfis*. (See his Obs. 88.) Jacquin describes it fifteen feet high, with round rough branches, rusty when old. *Flowers* small, white, without scent, in dense terminal *spikes*, two or three inches long. *Drupa* small, red.

8. *V. alba*. White-fruiting Varroia. Linn. Sp. Pl. 276. Jacq. Amer. 41. Wildd. n. 8 (Mepisus americana, alni vel coryl foliis, fructu magnifico albo; Comm. Hort. v. 1. 155. t. 80.)—Leaves heart-shaped, pointed, flowers cyanose.—Native of South America, about Carthagen and in Curavail. *A tree*, often thirty feet high, with an ample spreading head, and a trunk fix inches in diameter; though in hedges it is scarcely more than a shrub. *Leaves* four or five inches long, serrated, rough; somewhat heart-shaped at the base. *Cymes* large, not uncommonly extending fix inches, of numerous, white, scentless flowers. *Calyx* at first entire, but, as the corolla protrudes, it is pushed aside horizontally, splitting into two valves, the upper withering, the under permanent, and the margin is seen to have five very flight teeth. Limb of the *corolla* bell-shaped. *Drupa* oblong, measuring half an inch, whitish, filigulose, sweet, but inured and glutinous, eaten by the inhabitants of Curavail. *Nat. oblong, fritated, black.

9. *V. monotetra*. Single-flowered Varroia. Jacq. Hort. Schoenbr. v. i. 18. t. 39. Wildd. n. 9.—*Leaves* ovate; entire at the base. *Cymes* lateral. Flowers capitate.—Native of the Caraccas. It flowered in the hove at Schoenbrunn all summer long, and bore fruit. The *flum* is twelve feet high. *Leaves* three inches in length, flattened, ferrated from about the middle only. *Flowers* small, white, in little globular heads, collected into flattened cymes, which spring laterally from the branches, about half way between the leaves. *Calyx-teeth* triangular, scarcely pointed. *Corolla* bell-shaped, abrupt, crenate. *Stigmas* dilated, obtuse. *Drupa* scarlet, the size of a pea. There being but one kernel, it is probably owing to the plant not being in a natural situation, and therefore is wisely omitted by Willdenow in the specific character. For the fame reason, the name may probably prove exceptional.

In studying this genus, we cannot but observe that the species here mentioned are not precisely described, and nor so well defined, as could be wished, nor do we pretend to have placed them all beyond the reach of uncertainty, our materials being, in several instances, defective on the score of authority.

VARRONIAN SATIRE. See Satire.

VARS, in Geography, a town of France, in the department of the Charente; 6 miles N. of Angoulême.

VARS, a town of Imirretta; 10 miles S.E. of Cotatis.

VARTSETCH, a town of Ilfra; 8 miles E. of Pedena.

VARSHNEYA, in Mythology, a name of the Hindoo deity *Krishna*; which fee.

VARSOVIA, in Geography. See Warsaw.

VARU, an island in the Caribbean sea, near the coast of South America, about fifteen miles long, and three broad. N. lat. 10° 12', W. long. 75° 25'.

VARVELS, in Falconry, small rings about a hawk's leg, with the owner's name on them.

VARUNA, in Hindoo Mythology, is the genius or regent of the waters, corresponding with the Neptune of western heathens. As light is thought to be excluded from the deep, Varuna is also deemed the governor of the night, or of darkness; in this character, as well as in that of lord of punishment, coexisting with the Hindoo Pluto, who is named *Yama*; which fee. Still he is one of the twelve funes, called *Aditya*, of which fee under our article *Surya*.

As lord of punishment, the wealth of criminals is directed to be offered to him; or, in other words, thrown into the waters; or it may, instead, be bestowed on a learned priest. The latter, we may suppose, is likely, on most occasions, to outshine the deity. In the Institutes of Men, ch. ix. v. 243. 4. 5., these textes occur. "Let no virtuous prince appropriate the wealth of a criminal in the highest degree; for he who appropriates it through coutoufnets, is contamind with the same guilt. Having thrown such a fine into the waters, let him offer it to Varuna; or let him bellow it on some prief of eminent learning in the scripturn. Varuna is the lord of punishment; he holds a rod even over kings, and a prief who has gone through the whole Veda, is equal to a sovering of the world." In another text, c. ix. v. 365, it is said that "Varuna most especially binds the guilty in fatal cords." Like other Hindoo deities, Varuna has a comfort, or fakut, assigned him. She is called *Varuni*; which fee. He has likewise a terrestrial palace or paradise, situated far in the Weil,
VAS

Well, named Subhasvati; which fee. He has also had a terrestriall incarnation, under the name of Samvarua. 

VARUNI, the confort of the Hindoo Neptune, who is named Varuna; which fee. As well as his confort, he is said to be his daughter; a double relationship not uncommon with the gods both of India and Greece. 

VARUS, or VARUM FLUMEN, the Var, in Ancient Geography, a river, which, in the time of Strabo and Pliny, sepulted the Garaus from Italy. 

VARUSA, a river of Italy, in Gallia Cisalpina, which discharged itself into the Po, near the confluence of this river with the Ticin. 

VARUTHA, a town of Asia, in the Greater Armenia. 

PETOLY, in Geography, a town of Hungary; 10 miles S. of Munckacz. 

VARZEA, a town of Portugal, in the province of Beira; 9 miles S.S.W. of Lamego. 

VARZESKOI, a lake of Ruffia, in the government of Archangel; 60 miles E. of Mezen. 

VARZY, a town of France, in the department of the Nievre; 7 miles S.S.W. of Clamecy. 

VAS, Vessel. See VESSEL, VESICULA, and ANGIOLOGY. 

Hence, in the style of anatomists, the vasa adiopota, preparata, &c. 

VAS CHYLIFERUM, in Anatomy, the thoracic duct. See ABSORBENTS. 

VAS DEFERENS, the excretery tube of the testis. See GENERATION. 

VASA BREVIA, the short arterial and venous ramifications proceeding from the splenic trunks to the great end of the stomach. See ARTERY, and VEIN. 

VASA EFFERENTIA and INEFFERENTIA; the latter are the lymphatic vessels, which enter an absorbing gland; and the former, those which go out of it. See ABSORBENTS. 

The tubes which pass from the upper end of the testis, and unite to form the epididymis, are also called vasa efferentia. See GENERATION. 

VASA LATTA, or VENAE LATTEAS, the absorbers which take up the chyle from the small intestine. See ABSORBENTS, and INTESTINE. 

VASA VASIFORUM, the vessels which belong to the coats of vessels. See HEART. 

VASA CONCORDIAE, or HYDRAULIAE, are two vessels, so constructed, as that one of them, though full of wine, will not run a drop; unless the other, being full of water, do run also. Their structure and apparatus may be seen in Wolfius, Element. Mathet. tom. ii. Hydraul. 

VASA, in Geography, a town of Turkestan, on the Sird; 70 miles W. of Taraz. 

VASA, or Wafit. See WASA. 

VASAGUDA, or VASAGUDA, in Ancient Geography, a town of Africa, in Maurittania Cæsariensis. Potolomy. 

VASANTA, in Hindoo Mythology, is the name of the bofom friend of their Kama, god of love. Among the Maharat and low people he is called Beffant, Beffent, or Buffant. He is a personification of the season of spring; and fongs in his honour are chanted by minstrels of both sexes at vernal and other festivals. See under KAMA for some mention of his ineparable attendant. 

VASARCHELY, in Geography, a town of Hungary, on a small river, which runs into the Thyley; 50 miles N.N.W. of Temeswar. N. lat. 46° 25'. E. long. 29° 35'. 

Also, a town of Hungary; 22 miles E. of Cacchau. 

Also, a town of Transylvania; 40 miles E. of Colofvar. N. lat. 46° 37'. E. long. 25° 5'. 

VASARI, GIOVANNI, in Biography, was born at Arezzo in 1512, and was first inducted in design by a glass-painter, called Il Prete Callo, but afterwards, being taken to Florence by the cardinal Pafferini, studied under M. Angelo and Del Sarto. Another friendly cardinal conveyed him to Rome, the cardinal Ippolito di Mediæci; and under his protection he acquired riches and honours. In Rome he laboured affidiously, attaching himself particularly to M. Angelo, of whom he appears, by several letters preferred by Bottari, to have been very sincerely esteemed. He was employed in several public works at Rome, both as a painter and an architect, particularly in the Vatican, in the Sala della Cancellaria, where he painted, by the direction of the cardinal Farneæ, a series of frescoes, representing the principal actions of Paul III.; and in the church of S. Giovanni Dicollatto, he painted for the principal altar the mar-tyrdom of that saint, one of his most highly esteemed performances. 

He was invited by Cosmo I. to Florence in 1553, and employed by that prince as superintendant of the important works then going on in the Palazzo Vecchio, where he executed, with the help of numerous discipiles, the decoration of the principal apartments. Of his paintings there, pope Clement VII. crowning the emperor Charles V. was the most important, and it was accompanied, in other compartments in the fame hall, by representations of the actions of that monarch. 

There are many other works of Vasari scattered about Italy, as at Bologna, Arezzo, and Rimini, &c.; but for all he was a tame copyist of Michel Angelo's manner, and a very indifferent colourist. He is far more endeared to us by his writings than his pictures. His work, entitled "Lives of the most excellent Painters, Sculptors, and Architects, from the Period of Cimabue till his own Time," is the fountain of knowledge concerning the greater part of them: and though in many points he appears to have been too facile of belief, and to have related histories without sufficient inquiry into their correctness, yet upon the whole the world is indebted to him for an ingenious and useful work; without which, the history of the art would not now have been so distinctly understood, nor the profeffion so justly known and honoured. It was first published at Florence, in two volumes, in 1550, and afterwards republished with considerable additions, and heads engraved in wood of most of the artificers mentioned, in 1568, and has since been re-edited with copious notes by Bottari. Vasari died at Florence in 1576, at the age of 64. 

VASAVA, in Mythology, a name of the Hindoo god Indra; which fee. 

VASBARRA, in Ancient Geography, a town of Africa, in the interior of Mauritania Cæsariensis. Potolomy. 

VASBUHL, in Geography, a town of the duchy of Wurzburg; 4 miles N.E. of Arnlein. 

VASCO, or VASQUEZ DE CASTILLO, in Ancient Geography, a town of Gallia Narbonensis, according to Potolomy and Pliny. 

VASCONEZ, a people of Hispania Citerior, at the foot of the Pyrenees. These people, who in later times passed into Gaul, where they affinied the name of Gascon, lay to the east of the Cantabri; in the country now called Navarre; and they emigrated from the Pyrenees as far as the Iberus towards the south. Their principal towns were: Pompélio, Calaguris, and Graecuris. 

VASCULAR, VASCULARIS, in Anatomy, is applied to any thing consisting of divers vessels, veins, arteries, &c.

We say, the vascular and vesicular texture of the lungs.
All the flesh, in an animal body, is found to be vascular, none of it parenchymous, as the ancients imagined.

Vascular Glands. See GLAND.

Vascular, Vascularis, in Antiquity, was the denomination of a kind of artificers among the ancient Romans; who made silver and gold vases without relieves, or figures embossed on them.

Hence, according to Salamnus, it is, that Cicero, in his sixth oration against Verres, distinguished *vascularius from cultrarius from cultrator, engraver.*

In the art called by the Greeks καλλιτέχνης, which was the art of superadding ornaments of precious stones, or rich metals, to vases of other metals; the vascalarii and eculatii were different; the first being the goldsmiths who made the vase; the second, the sculptors who added the ornaments. But in the art called *τσαλτικής* or the art of cutting bas-reliefs, or flamping figures on metal, the vascalarii were also eculatii, or engravers; that is, they who made the vase, made also the relieves, or figures, with which it was enriched.

VASCULIFEROUS PLANTS, in Agriculture and Gardening, are all such as the seeds of which are contained in vials, divided in the cells. There are several of these in both these departments. See SEED.

VASE, a term of equal import with the Latin vas, whence it is formed; and with the English vessel; which see.

It is applied to the ancient vases dug from under ground, or otherwise found, and preferred in cabinets, &c. as vases of sacrifice, urns, &c.; and to other more modern vials, which are rather of curiosity and thow than use; as those of crystal, porcelain, &c.

In the curious collection of ornamental works, made by Meffrs. Wedgwood and Bentley, after the antique, there are vases of various kinds; some formed of a composition of terra cotta, resembling agate, jasper, porphyry, and other variegated stones, of the vitreous or crystalline kind; others of black porcelain, or artificial basaltes, highly finished, with bas-relief ornaments; others of the painted Etruscan kind; and others again ornamented with encaustic paintings. The art of painting vases in the manner of the Etruscans has been lost for ages; however, these ingenious manufacturers set themselves to revive it; and, having carefully examined the original Etruscan vases, and having perused with attention the writings of the late count Caylus upon Etruscan antiquities, they were convinced that the colours of the figures could not be successfully imitated with enamel; and that their effects must chiefly depend upon the discovery of a new kind of enamel colours, to be made upon other principles, and to have effects essentially different from those that were then in use, and are of the nature of glafs: the Etruscan colours being burnt in, smooth and durable, but without any glassy luster. In consequence of this observation, and by a great variety of experiments, they invented a set of encaustic colours, not only sufficient to imitate the paintings upon the Etruscan vases, but to give the beauty of design the advantages of light and shade in various colours; and to render paintings durable, without the defect of a varnished or glassy surface. These encaustic colours may be applied with great ease and certainty; they change very little in the fire, are not liable to run out of drawing, are perfectly durable, and not glassy, and posses the advantages of enamel, without its essential defects.

Catalogue of Cameos, &c. by Wedgwood and Bentley, 1773.

VASES, in Architecture, are ornaments of sculpture, placed on socles, or pedestals, representing the vases of the ancients; particularly those used in sacrifice, as the praefentulum, hippocam, incense-pots, flower-pots, &c. and occasionally enriched with baso-relieves.

They are commonly placed there to crown or finish façades, or frontispieces. They are frequently also called acorioria; and are usually inflate.

In forming and decorating vases, fancy has great scope. Many excellent inventions of these ornaments are transmitted to us from the ancients. A vase differs from an urn, as it is in general of a more elegant contour, and is lofty; whereas an urn should be low and wide, and always covered.

Vitruvius mentions a kind of *theatrical* vases, made of bracts, or earthen-ware, called *echia, νυξίς,* (see ECHIA and VITRUVIUS); which they disposed in private places, under the steps and seats of the theatres, to aid and incrathe the reflection and renunciation of the actors’ voices, &c. It is said, there are also vases of this kind in the cathedral church of Milan.

VASE is particularly used in architecture to signify the body of the Corinthian and Composite capitals; called also *tambour, or drum; and sometimes the conteneau, or ball.*

VASE is also formed upon vessels called *florula,* for what they otherwise call the *calyx.*

The vase, or rather calyx of a tulip, is the top or head of a tulip; the leaves of which form a kind of vase, or cup.

Goldsmiths, briners, &c. also use vase for the middle of a church-candlestick; which is usually of a roundish figure, bordering somewhat on that of a vase.

VASE River, in Geography, a river of America, which runs into the Mississippi, 55 miles above the mouth of the Ohio.

VASEN. See WISEN.

VASH, a river of Grand Bucharistan, which gives name to the country it waters; and runs into the Gihon near Terned.—Also, a province of Great Bucharistan; which see.

VASHAVAN, a town of Hindoostan; 30 miles S.W. of Dindigul.

VASHGERD, a town of Grand Bucharistan, and principal town of a district watered by the Vafh; 200 miles S.E. of Samarcand. N. lat. 38° 25’. E. long. 67° 50’.

VASHON’S ISLAND, an island near the west coast of America, at the bottom of the Admiralty Inlet, and eastern branch of the gulf of Georgia. N. lat. 47° 16’. E. long. 237° 25’.

VASIL, a town of Russia, in the government of Nizgorod, on the Volga; 60 miles E. of Niznei Novgorod. N. lat. 56° 16’. E. long. 45° 44’.

VASILICA. See BAMLICA.

VASIKLOV, a fort of Russia, in the government of Kiev; 28 miles S.S.W. of Kiev.

VASINA, a town of the island of Corfica; 4 miles N. of Balta.

VASIR. See SIRVENT.

VASISHTHA, in Biography, is the name of a celebrated perfom of Hindoo history and mythology; one of a class called Rishi, meaning a sage. Of these divine persons we have given a list, and some remarks, under the articles RISHI and KRITIKA; the latter being the Pleiades of the Hindoos, who have many very curious tales of their *fledging sweet influences.* Vasi.tha is a character frequently mentioned in the romantic histories of the Hindoos, as being referred to for advice by royal and other persons requiring spiritual or other consolation. He is, indeed, called the preceptor of the inferior gods. A very celebrated commentary on the Veda, the Hindoo scripture, is ascribed to Vasi.tha. It is in prose, with poetry intermingled; and is quoted as high law authority. (See VEDA.)
His wife, named Arundhati, is represented to have been exemplary in regard to holiness and sanctity, and to have been translatel to the skies with her faithful husband: she is still quoted as proverbial for virtue and constancy. Vasistha is a star of the second magnitude, in N. lat. 60°, and Arundhati is a smaller star near it.

In the Agni Purana, a hymn is addressed to Vasistha; affording some clue to the relative antiquity of the poetical romances bearing the common denomination of Purana; which fee.

VASUU, or VASIT, in Geography, a town of the Arabian Irak, on the Tigris. This town was built in the beginning of the eighth century, by Al Haraj, the Arabian general. A mint was established, and in 707, money was coined there by order of the caliph. In 1420 it was plundered by Timur Bec; 96 miles S.E. of Bagdad. N. lat. 32° 18'. E. long. 45° 38'.

VASKINA, a gulf or bay of Ruffia, on the south coast of the island of Kaluguev.

VASKOVNIA, a town of Ruffia, in the government of Piskov; 120 miles S.S.E. of Piskov.

VASLUI, a town of European Turkey, in Moldavia, on the Bria; 32 miles S. of Jaffy. N. lat. 46° 42'. E. long. 27° 35'.

VASLOKI, in Hindoo mythological Legend, is a name of a petty vassal, more commonly called Stha; which see.

The name of Vasloky, however, frequently occurs in the extravagant legends of the East. See BALIYA and KURMA-VAATAA.

VASON, in Geography, a town and cañon of Hungary; 20 miles W.S.W. of Stuhl Weissenburg.

VASPINCE, a town of Perfia, in the province of Ader-beizan, containing about 600 houses; 9 miles from Tabris.

VASQUEZ, a town of the island of Cuba; 66 miles N.W. of Villa del Principe.—Allo, a river of Mexico, which runs into the Spanish Main, N. lat. 11° 30'.

VASSAL, VASSALLUS, in our Ancient Customs, a person who vowed fidelity and homage to a lord, on account of some land, &c, which he held of him in fee.

Du-Cang will have the word to come from vaflus, which anciently signified a servant or domestick of a prince, and sometimes also the comte, or officer, in public trials. Menage, after Cuias, takes vaflal to have been formed of geif, an ancient German word, signifying companion. Cafe-neuvers derives it from the Gaulish geifus, a brave man, from geifi or geifum, or geifum, a kind of javelin used among them. Volusius derives vaflal from vas, vadas, pledge; whence also he will have it to be, that they are sometimes called fideles.

The vaflal was also called piratus, lord's-man, and fee-man; but now the denomination is changed into that of tenant in fee.

Accordingly the vaflal, or feudatory, was only another name for the tenant or holder of the land; though, on account of the prejudices we have juftly conceived against the doctrines that were afterwards grafted on this syllen, we now use the word vaflal opprobriously, as synonymous to slave or bondman. The manner of the grant, on the part of the proprietor or lord, who retained the dominion, or ultimate property of the feud, or fee, was by words of gratuitous and pure donation, dedi et concefi; which are still the operative words in our modern inquisitions, or deeds of feoffment. This was perfected by the ceremony of corporal in-vestment, or open and notorious delivery of possession, in the presence of the other vaflals, which perpetuated among them the era of the new acquisition, at a time when the art of writing was very little known; and, therefore, the evidence of property was reposed in the memory of the neighborhood: who, in case of a disputed title, were afterwards called upon to decide the difference, not only according to external proofs, adduced by the parties litigant, but also by the internal testimony of their own private knowledge.

They sometimes also used the term vaflal for vaflal; whence vaflory.

If a vaflal offended his lord grievously, either in person or in honour, he committed the crime of felony; which carried with it a confiscation of his fee.

VASSAL, a Rear, is he who holds of a lord, who himself is vaflal of another lord.

VASSAL was anciently used for soldier; by reason fees, at first, were given to none but military men.

VASSALAGE, the state of a vaflal; or a servitude and dependency on a superior lord.

Anciently, they distinguished between liege vaflalage, and simple vaflalage.

Lige vaflalage only belonged to the king; as carrying with it an obligation on the side of the vaflal to serve his lord in war, against all persons whatever. See LIEGE.

In all simple vaflalage, the fealty, or liege vaflalage, was still referred to the king.

Some also distinguished active vaflalage, and passive: the first is the right of fealty residing in the lord; the second, the service and duties incumbent on the tenant.

VASSALBOROUGH, in Geography, a town of the county of Maine, on the Kennebeck; 104 miles N.E. of Bolton.

VASSEN, or WASENN, a town of Holland, in the department of Guelderland; 12 miles S. of Hattem.

VASSIETTE, a river of America, which runs into Lake Michigan, N. lat. 44° 38'. W. long. 85° 18'.

VASSY, a town of France, in the department of the Calvados; 8 miles E. of Vire.—Allo, a town of France, and seat of a tribunal, in the department of the Upper Maene. In the year 1562, a bloody persecution against the Protestants began in this town; 9 miles S. of St. Dizier. N. lat. 48° 30'. E. long. 5° 2'.

VASTAN, a town of Curditan, on lake Van. In 1386, it was taken by Timur Bec; 20 miles S.W. of Van.

VASTANFORS, a town of Sweden, in Westland; 32 miles N.N.W. of Stroemhoff.

VASTAUNA, in Ancient Geography, a town of Asia, situated in the S.E. part of the lake Artsia, towards the 33rd degree of latitude.

VASTO, in Laos, a writ that lies against the tenant for life, or years, for making waife.

VASTUS, in Anatomy, the name of two very large muscles belonging to the thigh. The body of the femur is completely enveloped, except at the linea alpera, by a thick muscular mass: this may be distinguished at its origin into three portions, which soon became blended together, so as not to admit of separation. The part which covers the outside of the bone is called vastus externus; that which covers the inside, vastus internus; and the middle, vastus, or cruratus. These have usually been described as three distinct muscles; but some modern anatomists have more properly considered them as one, under the name of triceps femoris: they form the tri-femoro-rotulian of Dumas.

The triceps cruris then is a very thick illferior mass, of a rounded or convex figure, covering the thigh-bone, and extending from the bales of the trochanter to the patella and tibia.

The anterior surface is covered, towards the outside, by the tendon of the gluteus maximus, the tenfor vagus, the arteteria.
fascia lata, and the short portion of the biceps; at the middle, by the iliacus internus, rectus extensor cruris, and the external circumflex veins; on the infiie, by the factorius, the femoral artery, and the fascia lata. The posterior surface covers the body of the femur, with the exception of the linea aspera; it is attached to the anterior, external and internal surfaces of the bone, from the bases of the trochanters to within four fingers breadth of the knee; then it is separated from the femur by a loose and fatty cellular subsidence, and lastly, it covers the synovial membrane of the knee-joint.

The outer margin is fixed to the rough line, which descends from the great trochanter to the linea aspera, together with the gluteus maximus, to which it is closely connected: it is then fixed to the external edge of the linea aspera, in its whole length, and to the upper two-thirds of that line, which descends from the linea aspera to the external condyle of the femur, being connected in the latter situation with the fascia lata. The internal edge is fixed to the corresponding inner edge of the linea aspera, from the trochanter minor downwards; and to the upper two-thirds of the line, defending from it to the external condyle, being connected here with the tendon of the triceps sartorius. Its upper extremity is divided into the three portions already mentioned. The external (vastus externus) and most considerable is fixed to the circumference of the basis of the great trochanter; it descends on the outside of the thigh, increasing in size to the middle of the limb, and then diminishing again. At first it is separated from the middle portion by a thin stratum of cellular subsidence; but they are soon confounded in one mass. The internal portion (vastus internus) is not in general very distinct from the middle. Commencing at the root of the little trochanter, it descends on the inside of the femur, first increasing in size, and then diminishing again. On its outside, it is separated from the middle portion, if at all, by a very slight cellular line, for about an inch or two, after which they are confounded in one mass. The middle and smallest division (cruralis) commences at the basis of the neck of the thigh-bone, by an attachment to the rough line, which reaches from the great to the small trochanter; it descends perpendicularly, increasing in size, separated at first from the lateral portions, but soon inseparably joined with them into one mass, surrounding the body of the femur, and ending in a tendinous extremity, attached to the bases and sides of the patella, and to the tubercles of the tibia (tibiae). The back-mentioned attachment is effected by means of a broad and thick tendon, connected in front to that of the rectus extensor cruris, and expanded laterally into aponeuroses fixed to the tubercles of the tibia. Of these aponeuroses, the outer is closely connected to the fascia lata. The tendon of the triceps is divided above into three broad portions, which ascend on the three divisions of the muscle. A thick and broad aponeurotic sheet commences from the basis of the trochanter major and the linea aspera, and covers the upper half of the vastus externus: a similar but smaller aponeurosis descends from the linea aspera on the vastus internus. The muscular fibres of the vastus externus pass obliquely downwards and forwards from its superior aponeurosis, and from the aponeurotic septum, which separates it from the short head of the biceps to the inferior tendon. Of these fibres, the upper are the longest and most perpendicular; the succeeding ones become more and more oblique, and the lowest approach to the transverse direction, accompanying the tendon to within an inch of its termination.

The flabby fibres of the vastus internus pass with a corre-

fponding obliquity between the two aponeuroses; the inner or anterior being the longest and straightest, the lower shorter, and more transverse. Of the middle portion, the muscular fibres are parallel to the axis of the thigh, arising from the anterior and lateral surfaces of the bone, and terminating in the lower tendon.

A prolongation of the synovial membrane of the knee extends for some distance behind this portion, above the patella, and thus supplies the place of a bursa muscosa. The lateral portions of the inferior tendon adhere very closely to the synovial membrane of the knee.

The triceps femoris frays the knee-joint, either by moving the leg forwards on the thigh, or on the leg. These are very important muscles in progression, when they bring the thigh forwards on the leg of the advanced limb. When we are descending an inclined surface, and the heels slip, they make a great effort, by drawing forwards the thighs, to prevent the body from falling; in this exertion the patella is sometimes fractured. In standing, they preserve the thigh-bones perpendicular over the legs. They extend the leg on the thigh, where the limb left behind in progression is advanced in its turn in front of the foot which has just detached the ground.

VASU, in Hindu Mythology, a name of the regent of the winds, more commonly called Pavana; which see. But the word occurs more frequently in the plural, when "the Vaus" seem to imply the eight winds collectively; the Hindoos having many fables connected with this number of winds. It is not easy to discriminate at all times between the Vaus and the Maruts of the Hindoos. See Marut.

VASUDEVA is the name of the mortal father of their god Krishna: his mother was Devaki. (See KRISHNA.) The name Vasudeva is said to mean giver of wealth. Krishna himself is sometimes called by this name.

VASUGAN, in Geography, a river of Ruffia, which runs into the Oby, N. lat. 59°: E. long. 80° 14'.

VAT, in Commerce, &c. See FAT.

VAT, or Vat, in Mineralogy, denotes a square hollow place on the back of a calcining furnace, in which they lay the next serving of tin-ore to dry, before it is let down into the furnace, into which it passes through a plug-hole in the bottom of this vat, or dry.

Vatable, or GASTEBEF, Francis, in Biography, was born at Gamache, a village in Picardy, and having first distinguished himself in Greek literature, and by a translation into Latin of Aristotle's "Parva Naturalia," devoted himself to the study of the Hebrew language, in which he excelled, and which he reformed in France. He was appointed Regius professor of Hebrew at Paris by Francis I., in 1531, and the lectures which he made on the Old Testament were delivered to large audiences. His brief and clear explanations of the literal meaning of the texts were preferred.
preferred by some of his hearers, collected by Robert Stephens, and added to his publication in 1545, of Leo Judae's Latin version of the Bible. But as they contained some free passages, they were condemned by the doctors of the theological faculty in Paris, who, imperfectly acquainted with Hebrew, reposed their confidence in the Vulgate. However, the university of Salamanca reprinted the text and notes in Spain, R. Stephens defended them against the Paris theologians, and they have since been approved by men of learning. He not only encouraged Clement Marot to translate the Psalms into French verse, but affiliated him in the undertaking. Vatable, though suspected of heresy, was an orthodox Catholic, and opposed the discipline and opinions of the Calvinists. He died in 1547, poffeated of the abbacy of Bellozane, Dupin.

VATAN, in Geography, a town of France, in the department of the Indre; 11 miles N.W. of Issoudun. N. lat. 47° 52'. E. long. 1° 54'.

VATERIA, in Botany, was so named by Linneus, in honour of Abraham Vater, professor of Medicine at Wittemberg, and author of Catalogus Horti Wittembergensis, (a mere catalogue,) as well as of some botanical differentiations, on the Balsam of Mecca, on Hippomann, &c. This gentleman was born in 1664, and died in 1751. He succeeded his father in the profession. He died in 1754, aged eighty-one, and was also a naturalist. — Linn. Gen. 269. Schreb. 359. Mart. Mill. Dict. v. 4. Juff. 258. Lamarck Ill. t. 475. — Clafs and order, Polyandria Monegina. Nat. Ord. akin to Gutifera, Juff.

Obf. Retzius and Vahl have removed this plant to Eleocarpus, see that article; but without giving any sufficient reason. On the contrary, they describe the petals as entire; nor have they thrown any light upon the fruit, which, as described in the Hortus Malabaricus, cannot accord with Eleocarpus. The large figure, on the right hand, in that book, cannot be reconciled with the ref}, unless it be a seed vegetating. Jussieu seems staggered as to the character of this fruit, by finding the rudiments of three seeds in the germen. But this may very well be, and yet only one may ever come to perfection. The name learned author remarks, that Linneus, in his Systema, attributes three seeds to Vateria. This is true; but we believe it a typographical error, originating in the tenth edition of Systema Naturae, especially as the synoptical table, at the head of the clafs, renaments with the character of a single seed. This contradiction, whichever of the two characters be correct, is heedfully perpetuated through every following edition. On the whole, there appears more reason to retain than to abolish the genus in question.

1. V. indica. Copal Vateria. Linn. Sp. Pl. 734. (Eleocarpus copalifforus; Retz. Obs. Syst. 4. 27. Vahl Syst. v. 3. 67. Willd. n. 5. Penn. Rheede Hort. Malabar. v. 4. 33. t. 15.) — Native of Malabar and Ceylon. A tall and handsome tree, generally sixty feet high, with wide extended branches, and a thick bark, when wounded discharges a clear, pellucid, fragrant resin, acrid and bitter to the taste, at length becoming yellow and brittle like glass. This, according to Koenig, is one kind of Copal; see that article. Perfumes experienced in the use of this gum, so useful for varnishing anatomical preparations, know that there are, as Koenig says, several different things imported under the same name, which are not all equally soluble, even in oil of lavender. The leaves of this tree are alternate, hard, a plan long, elliptical, acute, coriaceous, entire, smooth. Flowers in large terminal, downy panicles, white with yellow filament; their scent sweet, like a lily. Fruit the size of a walnut in its green coat, swelling and blunt at the extremity, dark purple; its kernel white, bitterish and rather astringent, inclosed in a reddish skin, like that of a filbert. This description, taken from the Hortus Malabaricus, is precise; and as nothing is said of any hard shell, we do not see how the fruit can agree with that of Eleocarpus. The above-mentioned kernel, triturated with hot water, is reckoned strengthening to the stomach, and is given to stop vomiting or nausea.

Having formerly examined at sir Joseph Bank's a speci- men of Vateria, in order to distinguish this genus from VATICA, (see that article,) we have corrected the generic characters from observations then made, particularly respecting the authors, of which Retzius and Vahl have also given a faithful account. Linneus had no specimen, but described the genus from one in Hermann's herbarium, now at sir Joseph Bank's. Vahl is surely miftaken in saying the corolla and fruit agree with Eleocarpus!

VATES, in Mythology, the name of a clafs of Druids. VATHI, in Geography, a town on the north coast of the island of Samos, in a bay called the Gulf of Vathi. N. lat. 37° 49'. E. long. 26° 54'.

VATHIA, or BERRATHI, anciently Tyrus, a town of Europe, in the Morea; 16 miles N.E. of Napoli in Romaneia.

VATI, a town of the island of Siphonito. N. lat. 36° 57'. E. long. 24° 40'.

VATICA, in Botany, an unexplained name of Linneus, apparently derived from the same source as vestica, a prophesying. Hence the writer of the present article ventured the genus from one in Germania's herbarium, now at sir Joseph Bank's. We are sure it must have been brought. This conjecture appears in the form of a general opinion in Dr. Theiss, strengthened by a reference to Boehmer's Lexicon, p. 228, a book not within our reach. Now, with regard to this plant, whether it be from China, the specimens being imported India, just like many others, known to have been received from Java by Linneus. In fact, these specimens are of like Vatica (see that article) in appearance and character, that if it were possible to suppose the authors could vary so remarkably, we should suspect these plants might be only sexual differences of one species. Having started this difficulty without having the means of overcoming it, we proceed to describe VATICA.—Linn. Mant. 2. 157. Schreb. Gen. 318. 841. Willd. Sp. Pl. v. 2. 847. Mart. Mill. Dict. v. 4. Sin. Plant. l. 36. Juss. 259. Lamarck Ill. v. 397. — Clafs and order, Diocandria Monegina. Nat. Ord. akin to Gutifera, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, in five deep, erect, ovato-lanceolate, acute segments. Cor. Petals five, feffile, obovate, entire, three the length of the calyx, folded over each other, in some flowers to the left, in others to the right; their inner surface smooth; outer, in the expanded half, hoary. Stam. Filaments none; anthers fifteen, feffile, three on the base of each petal, small, ovate, fras citizen.
VAT

four obtuse cells, the two outer cells terminated by a small, intermediate, upright spine, the two inner but half as long, without any spine. *Pfl. German superior, conical, with five angles, obtuse, hoary; fylle cylindrical, with five angles, twisted; stigma bluish, obscurely three-lobed. *Puric. unknown, but the germen has three cells, with the rudiment of a foliary seed in each.

Wild. n. 1. Sm. Plant. t. 36.—Native of China, according to Linneaus, but his authority, as we have faid, does not appear. This seems to be a tree, very near *Vateria indica, from which it chiefly differs in the number and form of the flaments. As to the fruit, Jullien's having found three cells and as many seeds, in the germen of *Vateria, renders the supposed difference in the ripe fruit very doleful. The leaves, inflance, &c. Willd. flange, &c. are clothed with the fame fine, short, clofe, hoary pubefcence, in both. It is much to be wished that some East Indian botanift would clear up these doubts respecting two very fine, and hitherto little-known plants. We must add, that if this be *Vateria, nothing can be more different in its peppers from *Elaocarpus; for instead of the thin texture, and curiously laminated Fragment, appropriate to the latter, their thick undivided substance, and partial hairiness at the back, prove that these genera ought never to be confounded together.

Vatica, in Geography, a sea-port town of European Turkey, in the Morea, situated in a large bay, to which it gives name; 44 miles S.E. of Miftra.

VATICAN, VATICANUS, is properly the name of one of the seven hills on which Rome stands; on the foot of this is the famous church of St. Peter, hence called the Vatican; and a magnificent palace of the pope, which has the fame denomination. Hence arife divers figurative expressions; as the thunderbolt of the Vatican, &c. the pope's anathema, &c.

The word, according to Jeffieu's Dictionary, is derived from vaticinium, prophecy; by reafon of the oracles and predictions which were used to be delivered there by the inspiration of an ancient deity, called Vaticauns; who was supposed to unbend the organs of speech in new-born children; and whom others will have to be no other than Jupiter, confidered in that capacity.

Vatican, The Library of the, is one of the most celebrated in the world; it is particularly remarkable for its manuscripts. It was firft erected, according to Petavius (Rat. Temp. lib. ix. cap. 9.) by pope Nicholas V., who succeeded to the papal chair in 1447. It was re-established, after the books had been deftroyed, under the pontificate of Calixtus III.; by Sixtus IV.; and after having been almoft entirely deftroyed by the army of Charles V. it was not only refored to its former flate by Sixtus V., but greatly enriched with books and manuscripts. It was finally fixed in the Vatican, under the pontificate of Martin V.

Towards the beginning of the 17th century, it was greatly augmented by the addition of that of the elector palatine, which is open to all the world three or four times a week. In it are fiven a Virgil, Terence, &c. above a thousand years old; as also the manucript on which the edition of the Septuagint was made; and abundance of rabbinical manuscripts.

Vatican Manuscript, is one of the most celebrated manucripts of the Greek version of the Bible now extant in the world. It was published at Rome by cardinal Carafa, at the command of Sixtus Quintus, in 1587; and in the preface, it is laid to have been written ante millenium ducen-

tefumnum annum, i.e. before 387; but Blanchini supposes it a few years later. A Latin edition from this manuscript, with notes, was printed at Rome in 1588, by Flam. Nobilius; and an edition, with the Greek and Latin, with the division of the verses according to the Vulgate, and Nobilius's Latin notes, and the Greek exegia of Carafa, by J. Morinus, at Paris, in 1628. This manuscript is written in large or text letters, and has no distinguishing chapters, verses, words, nor any marks of accents. It is mutilated both at the beginning and end; and wants the firft forty-fix chapters of Genesis, thirty-two Psalms, &c. from the 105th to the 137th, and the latter part of the Epitile to the Hebrews, from chap. ix. ver. 14, with the other Epitiles of Paul to Timothy, Titus, and Philemon, and the whole book of Revelation. It appears also, that the whole manuscript has been repaired, with fresh ink laid over the letters which were disappearing through age. In the edition of Carafa, the mutilated passages have been suppled from other copies.

It has been averted, by two eye-witneffes, that this manucript has undergone fome alterations by a later hand. See Le Long's Biblioth. Sacra, cap. 3. fect. 4. and Wetstein's Prolegomena. Nov. Teft. p. 24.

It is difficult to cftimate the comparative value of this and the Alexandrian manuscript, in which thirty Psalms, a few chapters, and a few verses, are now loft, as well as parts of verses in different places; and in which there have been fome rufures and interjections, as Grabe allows. If, as Grabe fates it, that manuscript be the moft refpeetable, which comes the nearest to the Hexaplar copy, the Alexandrian manuscript feems to claim that merit in preference to its rival. But if it be thought a matter of superior honour to come nearer the old Greek version, unaltered by Origen, that merit feems to belong to the Vatican. For further particulars, fee the Prolegomena of Walton, Grafe, Wetstein, Mills, and Le Long, 4to supra.

VATICANA PHILIPPI, the name of an old form of medicine, intended as a purge. The recipe is in the old London Pharmacopoeia; but the late ones have discarded it.

VATICANO, CAPE, in Geography, a cape on the W. coast of Calabria Ultra. N. lat. 38° 40'. E. long. 16° 52'.

VATICINATION, VATICATIO, the act of prophesying, or divining. See DIVINATION, and PROPHESY.

VATIMONT, in Geography, a town of France, in the department of the Mofelle; 8 miles W.N.W. of Morhange.

VATISIA, or FATISIA, a town of Afiatic Turkey, in the government of Sivas; 90 miles N. of Sivas.

VATO, a town on the W. coast of the ifland of Negro-pont. N. lat. 38° 20'. E. long. 24° 2'.

VATRANDEL, a town of Hindooftan, in the Carnatic; 4 miles N. of Vellore.

VATTIER, Peter, in Biography, an Arabic Schollar, was born at Lizeieux, in Normandy, and having been educated for the medical profession, was appointed physician and counfellor at Galton, duke of Orleans, brother of Lewis XIII. To an extensive acquaintance with the Arabic, Persian, and Turkish, both Greek and Latin, he added a peculiar attachment to Arabic writers, and translated many of their works. Among these are “The Hahometan History, or the Forty-nine Caliphs of Elmacin”; “The History of the Great Tamerlane, from the Arabic of Acheam, Son of Guerafo;” “The Egypt of Murtaf;” “The flegy of Tograi, with some Sentences from the Arabic Poets;” &c. He also wrote a work, entitled “ Nouvelles Perfees la Nature des Pfaffions,” 1659, 4to.

The time of his death is not known. Moreri.

VAVANGA, in Botany. See VANGUERIA.

VAVAO,
VAVAO, or Vavou, in Geography, one of the Friendly Islands, in the South Pacific ocean, seen by Peroufe in 1787, who says, "this island, which Cook never visited, is almost equal in size to Tongataboo, and has the advantage of being never in want of water, with a good harbour." It had been before discovered by the Spanish pilot Maurelle, and with a number of islands almost as considerable as those already explored by Capt. Cook, who called the islands of Majorca. S. lat. 18° 34' of the western point. See Tonga.

VAVASOR, VAVASOR, Valvasor, or Valvasure, in our Ancient Coursienis, a diminutive of valvasor, or valvour; signifying a valfa of a valfali, or one who held a fee of another valfali.

Yet Camden, and others, hold vavasor to be a dignity, next below that of a baron; he adds, that the word is formed of vas fortis ad vladusunem, a vessel chosen for safety and health. Others derive it à valva, quibus obligatus sit ad fines ad valvam domini, vel indignus sit cæi intrare; as being a person obliged to wait at his lord's door, or as un worthy to enter thereat; but this etymology is ridiculous enough.

Du-Cange distinguishes two sorts of vassals under this denomination: the great, called valvasores, who held of a king; such were counts and barons: and the lesser, called valvasorini, who held of the former.

The vassals are mentioned by our ancient lawyers as viri magna dignitatis; and sir Edward Coke speaks highly of them. But they are now quite out of use; and our legal antiquarians are not agreed upon even their original or ancient office.

VAVASORY, VAVASORIA, the quality of the land, or fee held by a vavasor.

"Quod dictitur de baronia non est observandum in vavasa toria, vel aliis minoribus feudis quam baronia, quia caput non habent ficut baronia." Bract. lib. ii. cap. 39.

There are base vavasories, and frank or noble vavasories; according as it has pleased the lord to make his vavasor. Base vavasories are those for which the lord of the fee owes fummage, light-horse, rents, or other services. Free vavasories are such as are exempt from these services.

VAVASSEUR, FRANCIS, in Biography, was born in 1605, at Paray, in the diocese of Autun; and entering into the society of the Jesuits in 1621, and acting as regent in the schools for some years, he was called to Paris to occupy the chair of positive theology, the duties of which he discharged honourably for thirty-six years; and he died in this city in 1681, aged seventy-six years. He has been reckoned one of the most elegant and correct Latin writers, and wrote several theological pieces, some against Janensium, and one of a singular subject, "On the personal Beauty of Jesus Christ," and also poems chiefly on sacred subjects. The work which has chiefly distinguished him is a treatise "De Ludicia Diuicione," or on the burlesque style, dedicated to Balzac. He also wrote a treatise "On the Epigram," and "Remarks on the Poetics of Father Rapin." Morei.

VAUBAN, SEBASTIAN LE PRESTRE, Seigneur de, marshal of France, and an eminent engineer, was born in 1633, and began to hear arms at the age of seventeen under the prince of Conté, general of the Spanish army. Being taken prisoner by a French party, he was engaged by cardinal Mazarin on the royal side, and employed in 1653 at the second siege of St. Menehould, by which it was recovered to France. He also acted as engineer in the five following years at several other sieges. After the peace of the Pyrenees, he was employed in demolishing some places and fortifying others; and he also executed a variety of ideas, by the maturity and development of which he contributed in a high degree to the improvement of the science of fortification. On the renewal of the war in 1669, he conducted several sieges, at which Louis XIV. attended in person, and he was commissioned to fortify several places, and in 1668 nominated governor of the citadel of Lille, which he had constructed. After the peace of Aix-la-Chapelle, he visited Piedmont, and gave designs to the duke of Savoy for some important fortresses. In the war of 1672 he again distinguished himself, particularly at the siege of Maeltricht, in which he introduced his famous method of attack by parallels and places of arms; and also on other occasions, when an opportunity offered for the display of his inventive genius. In carrying his schemes into execution he was anxious for saving life, and therefore preferred a slow and regular advance in sieges. The peace of Nimoguen afforded him leisure for fortifying towns; and of these, his master-piece was the port of Dunkirk. On the commencement of war, he again resumed his active services, and had the honour of taking Luxembourg, which was regarded as impregnable. Upon the whole, he fortified one hundred old places, constructed thirty-three new fortresses, and had the principal direction of fifty-three sieges. In recompence of his various exertions, he was advanced to several posts of honour, and in 1703 appointed marshal of France. At Dunkirk, whether he was sent in a state of great alarm, he died of a fluxion in his lungs, in March 1707, at the age of seventy-four years.

The character of Vauban, as a man and a citizen, was no less estimable than his superior talents and achievements in his professional capacity. Loyal and faithful to his sovereign, he fludied to serve more than to please; and he manifested on all occasions an inviolable attachment to truth. As a liberal and zealous patriot, he made such observations, and collected such facts in his various travels, as contributed most effectually to the improvement and prosperity of his country. These were comprised in twelve large MS. volumes, which he modestly denominated "Mes Observations," and Fontenelle observes of him in relation to these, that if all his projects could be executed, his "idleness" would be more useful than his labours. In 1699, he was nominated an honorary member of the Academy of Sciences. The following works were either written by himself, or in consequence of ideas which he suggested: viz. "Manière de Fortifier, par M. de Vauban, mije en ordre par le Chevalier de Cambrai," Amst. 1689 and 1692, printed at Paris under the title of "L'Ingenieur Francois," with notes by Albert, professor of mathematics; and afterwards with notes by the Abbé du Fay; "Nouveau Traité de l'Attaque et de la Défense des Places, suivant le Système de M. de Vauban, par M. Desprez de Saint-Sevin," Paris 1736; "Effais sur la Fortification, par M. de Vauban," Paris 1740; "Projet d'un Dime Royale," Rouen, 1707, often reprinted. This last work is attributed by Voltaire to Bois-Guillebert, author of a "Traité Politique" in the name of Vauban, Fontenelle Elodge. Morei.

VAUBECOURT, in Geography, a town of France, in the department of the Meuse; 6 miles N. of Bar-le-Duc.

VAUCHERIA, in Botany, was so named by M. Decandolle, in his Flore Française, in honour of the discoverer of the genus, the Rev. M. Vaucher of Geneva, author of an excellent work in quartos, entitled "Histoire des Coniferes d'Europe," where this genus is established by the name of Pinus; the latter appellation has very properly given way to the above, previously chosen by M. Decandolle.—Smith, Eng. Fl. Bot. v. 25. 1765. "Decand. Rapport fur les Conif.
adjoining to the anther, ovate, single-feeded, in pairs or
solitary.
(Ætoperferna effulsa; Vauch. Conf. 31. t. 2. f. 7. Conferva
veheata; Dillw. Conf. t. 74, without the anther. Ceramium
caepitulum; Roth Catal. v. 3. 120.)—Floating. Capsules
in pairs and solitary, effulsa on each side of the anther.
Found floating on the surface of pools, in large green patches,
about February; and consisting of capillary, branched,
smooth, rather cleft, tubular filaments, filled with a green
pulp fulvous, which separates in oblong portions, giving
the filament a jointed appearance. Capules lateral, seftile,
pellucid, commonly in pairs, each containing one large green
seed, and having next to them an awl-shaped body, affected
by Vaucher to be the anther. Yet sometimes this body
seems to shoot out into a branch. Vehicles are often found
on the branches, perhaps of the nature of galls, inhabited
by the aquatic animalcule called by Muller Cyclops Lulula,
in considerable numbers, with one dark-coloured animal
besides.
t. 1766. (Ætoperferna gerninata; Vauch. Conf. 29. t. 2.
f. 5.)—Floating. Capsules in pairs and solitary, on opposite
partial filaments, growing out of one common filak with the
anther. — Sent by Mr. W. Borer, along with the preceding,
from Suffey. The habit is the fame in both, but the fruica-
tion, furnished with partial filaments, and with a common
filak for both organs, appears to afford a good specific cha-
teristic. Some botanists nevertheless, and among them, if
we mistake not, Mr. Dillwyn, consider these two plants as more
varieties of each other.
3. V. velutina. Velvet Vaucheria. (Conferva velutina;
Linum. Sp. Pl. 1698. B. tenerissa viridis, velutum referens;
Dill. in Rauy Syn. 56. Mucf. t. 7. f. 14. B. terriratis
viridis herbaceae et mollissima, filamentos ramitos et non ra-
mois; Mich. Gen. 211. t. 89, f. 5.)—Erech, tufted. Fil-
aments beaded, somewhat rigid. Capsules seftile. — This
covers the earth, in moist shaded places, with a most beau-
tiful fine green velvet carpet, frantant like several of the
Jungermannia, even for a long time after it is dried. It ap-
pears to be perennial, occurring in summer as well as winter,
but has been thought more common than it really is, because
Dillenius and others have confounded with this plant a much
more general one, Conferva marifla, Engl. Bot. t. 1554,
which is prostrate, resembling fatin rather than velvet, and
has no sweet scent. M. Vaucher is our authority for re-
moving this species hither. Micheli has but imperfectly
figured the capules, and in fhuch a manner that they may
belong either to those Conferva which make Roth's genus of
Ceramium, or to Vaucheria. Of the anther we know
nothing.
We have here limited ourselves to the British species,
which may possibly prove but a small part of the genus,
when the subject has been sufficiently examined.
VAUCLA.IN, L. e, in Geography, a town of the island
of Martinico, situated in a bay on the N.E. coast. N. lat.
14° 30'. W. long. 60° 46'.
VAUCUCL. A town of France, in the department of
the Doubs; 8 miles S.W. of St. Hypolite.
VAUCLUSE, a town of France, in the department of
Orange, on the left hand of the Rhone, in N. lat. 44°,
one of the twelve departments of the S.E. region of France,
bounded on the N. by the departments of the Drôme and
Ardèche, on the E. by the department of the Lower Alps,
and the S. by the department of the Mountains of the
Rhône, and on the W. by that of the Gard. It is in the
appellation from the fountain of Vauche, (see Fontaine de
Vauches,) which is the source of the river Sorgues, and made
memorable by the near residence of Petrarch and Laura.
Its territorial extent is 3700 kilometres, or 186 square
leagues, and its population consists of 190,180 inhabitants.
It is divided into 4 circles or districts, 22 cantons, and
150 communes. The circles are, Orange, including 54,293;
Avignon, 47,351; carpentras, 39,714; and Apt, 48,822 in-
habitants. According to Hallenfraz, its length in French
leagues is 15, and its breadth 10: its circles are 4, its can-
tons 52, and its population consists of 200,500 persons.
Its capital is Avignon. Its contributions, in the eleventh
year of the French era, amounted to 1,157,701 francs;
and its charges, administrative, juridical, and for public in-
frtruction, were 227,109 francs, 14 cents. This department
consists of plains, marshes, gentle eminences, and hills.
Mont-Ventoux is upwards of 6000 feet above the level of
the sea. The soil is various, and indifferently cultivated.
The products are grain, silk, flax, and tobacco. In this de-
partment coal is exported in bundles with sulphur, and few metallic
fulbances, potter's-earth, mineral springs, &c.
VAUCOULEURS, a town of France, and principal
place of a district, in the department of the Meule; 8 miles
N.E. of Gondrecourt. N. lat. 48° 36'. E. long. 5° 44'.
VAUD, PAES DE, a country of Switzerland, of which
travellers and historians speak with rapture, particularly
of that part which borders on the lake of Geneva. It is almost
wholly a gradual ascent from the edge of the lake, richly
laid out in vineyards, corn-fields, and luxuriant meadows,
and chequered with continued hamlets, villages, and towns:
the shores are generally of the clearest gravel, and the water of
the finest transparency. This country is one of the two
great divisions into which the canton of Berne is divided;
the other being the German district. The Pays de Vaud, after
the decline of the Roman empire, made a part of the king-
dom of Burgundy, from which it fell to the empire of Ger-
many, under which the dukes of Zaringen held it as a fief,
and at the extinction of that family, it became annexed to
the cantons of the counts of Savoy. It was conquered from
the count of Savoy by Berne in 1536, and in
this year the reformation was introduced. From that period
the whole Pays de Vaud, excepting the common baillages
of Grenfon, Orbe, and a small portion of it which was ceded
to Frinburg, has been subject to Berne, and forms a part
of that canton. The German district was gained by conquest
from the cantons of the empire. In each of these divisions
justice is administered and taxes regulated by peculiar laws
and customs. Each division has its treasurer and chamber
of appeal resident in the capital; the chamber of appeal
belonging to the Pays de Vaud judges in the laft resort,
but the inhabitants of the German district may appeal to the
sovereign council. During the French revolution, the Pays
de Vaud was separat from the canton of Berne, and formed
into an independent republic under the protection of France,
in January 1798. In the new division of Switzerland, it
forms the canton or department of Leman, of which Lau-
flaine is the capital. The Pays de Vaud is estimated to be
about 60 miles long, and as many broad; bounded on the
N. by the county of Neuchâtel, on the E. by the canton
of Frinburg, on the S. by the lake of Geneva and the river
Rhône, and on the W. by France. It includes the towns
and bailiwicks of Lauffanne, Yverdon, Moudon, Avence, Ve-
vay, Morges, and several others.
VAUDE-
VAUDEMONT, a town of France, in the department of the Meurthe; 4 miles S. of Vezelise.

VAUDEVILLE, a song sung in the streets by ballad-fingers, the subject of which is generally jocose or satirical. The origin of this little kind of poem is traced up to the time of Charlemagne. But according to the more general opinion, it was invented by a certain man of the name of Baffelin, Foulon de Vere in Normandy; and in order to dance, as people used to assemble in the Val de Vire, they were called Vaux de Vire, and afterwards, by corruption, Vaudrevilles.

The air of these Vaudrevilles is generally very unmusical.

But as people merely listen to the words, the tune only helps to enforce the voice and render the words more audible. But, as music, there is in general neither tune, melody, nor measure in their tunes. The Vaudiville, with respect to the words, belongs exclusively to the French, and they are sometimes very piquant and pious. Roufseau.

VAUDIER, in Geography, a town of France, in the department of the Stura, late in the province of Coni; 5 miles S.E. of Demont.

VAUDOIS, VALENSES, or WALDENFES, in Ecclesiastical History, a name given to a sect of reformers, who made their first appearance about the year 1160.

Of all the facts that arose in this century, none was more distinguished by the reputation it acquired, by the multitude of its votaries, and the solemnity with which its bitterest enemies bore to the profanity and innocence of its members, than that of the Waldenses, so called, fays Mohheim, from their parent and founder Peter Waldus, or Valdus. They were also called Leonitis, from Leonis, the ancient name of Lyons, where their feet took its rise. The more eminent persons of that sect manifested their progress towards perfection by the simplicity and meanness of their external appearance; hence, among other things, they wore wooden shoes, which, in the French language, are termed fabots, and had imprinted upon these shoes the sign of the crofs, to distinguish themselves from other Christians; and on these accounts they acquired the denomination of Sabbatati and Infubbatati.

The origin of this famous sect, according to Mohheim, was as follows: Peter, an opulent merchant of Lyons, unfamed Valdus, or Valetius, from Vaux, or Waldum, a town in the marquisate of Lyons, being extremely zealous for the advancement of true piety and Christian knowledge, employed a certain priest, called Stephanus de Evita, about the year 1160, in translating from Latin into French the four Gospels, with other books of Holy Scripture, and the most remarkable sentences of the ancient doctors, which were so highly esteemed in this century. But no sooner had he perused these sacred books with a proper degree of attention, than he perceived that the religion, which was now taught in the Roman church, differed totally from that which was originally inculcated by Christ and his apostles. Struck with this glaring contradiction between the doctrines of the pontiffs, and the truths of the Gospel, and animed with zeal, he abandoned his mercantile vocation, distributed his riches among the poor (whence the Waldenses were called poor men of Lyons), and forming an association with other pious men, who had adopted his sentiments and his turn of devotion, he began, in the year 1170, to assume the quality of a public teacher, and to instruct the multitude in the doctrines and precepts of Christianity.

Buzza, and other writers of note, who are followed by Dr. Maclean, the learned translator of Mohheim's History, give different accounts of the origin of the Waldenses; alleging, that it seems evident from the best records, that Valdus derived his name from the true Valdenses of Piedmont, whose doctrine he adopted, and who were known by the names of Vaudois and Waldensian before his immediate followers existed. If the Waldenses or Waldensian had derived their name from an eminent teacher, it would probably have been from Valdo, who was remarkable for the purity of his doctrine in the eleventh century, and was the contemporary and chief counsellor of Ranulphius. But the truth is, that they derive their name from their valleys in Piedmont, which in their language were called vaux, and hence Vaudois, their true name; hence also Peter, or, as others call him, John of Lyons, was called in Latin Valdus, because he had adopted their doctrine; and hence the term Waldenses or Waldenfes, used, by those who write in English or Latin, in the place of Vaudois. The bloody inquisitor, Remerus Sacco, who exercised such a furious zeal for the destruction of the Waldenses, lived but eighty years after Valdus of Lyons, and must, therefore, be supposed to know whether or not he was the real founder of the Waldenses or Leonits; and yet it is remarkable, that he speaks of these Leonits as a sect that had flourished above five hundred years; and mentions authors of note to make their antiquity ascend to the apostolic age. See the account given of Sacco's book by the Jesuit Gritter, in the Bibliotheca Patrum. See also Leger's Histoire Gen. des Eglises Vaudois, cap. 25, 26, 27.

But to return to the history of Peter Valdus. Soon after Peter had assumed the exercise of his ministry, the archbishop of Lyons, and the other rulers of the church in that province, vigorously opposed him. However, their opposition was unsuccessful; for the purity and simplicity of that religion which these good men taught, the spotless innocence that shone forth in their lives and actions, and the noble contempt of riches and honours, which was conspicuous in the whole of their conduct and conversation, appeared so engaging to all such as had any sense of true piety, that the number of their followers daily increased. They accordingly formed religious assemblies in France, and afterwards in Lombardy, from whence they propagated their sect throughout the other provinces of Europe with incredible rapidity, and with such invincible fortitude, that neither fire, nor sword, nor the most cruel inventions of merceless persecution, could damp their zeal, or entirely ruin their cause.

The attempts of Peter Waldus, and his followers, were neither employed nor designed to introduce new doctrines into the church, nor to propose new articles of faith to Christians. All they aimed at was, to reduce the form of ecclesiastical government, and the manners both of the clergy and people, to that amiable simplicity, and primitive sanctity, that characterized the apostolic ages, and which appear so strongly recommended in the precepts and injunctions of the divine Author of our holy religion. In consequence of this design, they complained that the Roman church had degenerated, under Conftantius the Great, from its primitive purity and sanctity. They denied the supremacy of the Roman pontiff; and maintained, that the rulers and ministers of the church were obliged, by their vocation, to imitate the poverty of the apostles, and to procure for themselves a subsistence by the work of their hands. They conferred every Christian as, in a certain measure, qualified and authorized to instruct, exhort, and confirm the brethren in their Christian courts, and demanded the renunciation of the ancient pontifical dignities of the church, i.e. the exaction of tithes and offerings, which the new-invented doctrine of indulgences had almost totally abolished. They, at the same time, affirmed, that every pious Christian was qualified and entitled to receive the sacrament, the kind or degree of satisfaction or
expiation that their transgressions required; the confession made to priests was by no means necessary, since the humble offender might acknowledge his sins, and tell his repentance to any true believer, and might expect from such the counsel and admonition which his case demanded. They maintained, that the power of delivering sinners from the guilt and punishment of their offences belonged to God alone; and that indulgences, of consequence, were the criminal inventions of forbid avarice. They looked upon the prayers and other ceremonies that were intitulated in behalf of the dead, as vain, useless, and absurd, and denied the existence of departed souls in an intermediate state of purification; affirming, that they were immediately upon their separation from the body, received into heaven, or thrust down to hell. These, and other tenets of a like nature, composed the system of doctrine propagated by the Waldenses. It is also said, that several of the Waldenses denied the obligation of infant-baptism, and that others rejected water-baptism entirely; but Wall has laboured to prove, that infant-baptism was generally practised among them. Hift. of Infant-Baptism, p. 387, &c.

Their rules of practice were extremely austere; for they adopted, as the model of their moral discipline, the sermon of Christ in the mount, which they interpreted and explained in the most rigorous and literal manner, and, consequently, preached against, and condemned in their society all wars, and fruits of law, and all attempts towards the acquisition of wealth, the inflating of capital punishments, self-defence against unjust violence, and oaths of all kinds.

The government of the church was committed by the Waldenses to bishops, called also majorales or elders, presbyters, and deacons; for they acknowledged that these three ecclesiastical orders were instituted by Christ himself. But they thought it absolutely necessary that these orders should resemble the apostles of Christ, and be, like them, unlearned, poor, and furnished with some laborious trade or vocation, in order to gain by constant industry their daily subsistence; and indeed most of the Waldenses gained their livelihood by weaving; whence in some places the whole feft was called the feit of the weavers. The laity were divided into two classes, vis. the perfect and the imperfect Christians: the former divested themselves of all worldly possessions, manifested in the wretchedness of their apparel, their extreme poverty, and emaciated their bodies by frequent fasting; the latter were less austere, and approached nearer to the method of living generally received, though they abhomed from all appearance of pomp and luxury.

The Waldenses were not without intestine divisions; for such of them as lived in Italy differed considerably in opinion from those who dwelt in France, and the other European nations. The former considered the church of Rome as the church of Christ, though much corrupted; they acknowledged, moreover, the validity of its seven sacraments, and solemnly declared they would continue always in communion with it, provided that they might be allowed to live as they thought proper, without molestation or restraint. The latter affirmed, on the contrary, that the church of Rome had apostatized from Christ, was deprived of the Holy Spirit, and was in reality, that whore of Babylon mentioned in the Revelation of St. John. They were also divided in their sentiments concerning the polliess of worldly goods. In the fourteenth century, the Waldenses, though they were every where exposed to the fury of the inquisitors and monks, baffled all the attempts that were made to extirpate them. Many of them fled out of Italy, France, and Germany, into Bohemia, and other adjacent countries, where they afterwards associated with the Hussites, and other separatists from the church of Rome. In the fifteenth century they subsisted in several European provinces, more especially in Pomerania, Brandenburg, the district of Magdeburg, and Thuringia, where they had a considerable number of friends and followers; though, it is said, that many adherents of this sect, in the countries now mentioned, were discovered by the inquisitors, and delivered over by them to the civil magistrates, who committed them to the flames. After the Reformation, in the sixteenth century, the descendants of the Waldenses, who lived shut up in the valleys of Piedmont, were naturally led, by their situation in the neighbourhood of the French, and of the republic of Geneva, to embrace the doctrines and rites of the reformed church. So far down, however, as the year 1630, they retained a considerable part of their ancient discipline and tenets; but being much reduced by the plague in that year, and deprived of many of their clergy, they applied to the French churches for spiritual succour; and the new teachers, sent from thence, introduced several changes into the discipline and doctrine of the Waldenses, and rendered them conformable, in every respect, to those of the Protestant churches in France. In this century they suffered much from the persecution of Philibert Emanuel, duke of Savoy, who, at the solicitation of the pope resolved to force his subjects to return to the communion of the church of Rome; and in 1561 sent a Dominican friar, as an inquisitor, with forces to effect his purpose. After ineffectual supplications, they took up arms, and so far prevailed, after enduring very severe difficulties, as to obtain some degree of liberty and peace.

During the greatest part of the sixteenth century, those of them who lived in the valleys of Piedmont, and who had embraced the doctrine, discipline, and worship of the church of Geneva, were oppressed and persecuted, in the most barbarous and inhuman manner, by the inquisitors of Rome. This persecution was carried on with peculiar marks of rage and enormity in the years 1655, 1656, and 1696, and seemed to portray nothing less than the total extinction of that unhappy nation. The most horrid scenes of violence and bloodshed were exhibited in this theatre of papal tyranny; and the few Waldenses that survived, were indebted for their existence and support to the intercession made for them by the English and Dutch governments, and also by the Swiss cantons, who solicited the clemency of the duke of Savoy in their behalf. Mohelin's Eccl. Hist. vol. ii. iii. iv. Eng. ed. 8vo. Dupin's Eccl. Hist. of the Sixteenth Century, vol. ii. p. 414. VAUDREVANGE, in Geography, a town of France, in the department of the Meute, on the Sarre; formerly a considerable town, but ruined by the wars in Lorraine; 3 miles N. of Sar-Louis. VAUDREUIL, a town of France, in the department of the Eure. In 1195, the king of France besieged it, and Richard I. king of England, advancing to its relief, a battle ensued, in which the latter had the victory. Vaudreuil had formerly a royal palace; 4 miles N. of Louviers. VAUGELAS, in Biography. See Claude Favre. VAUGIRARD, in Geography, a town of France, in the department of Paris; 2 miles S.W. of Paris. VAUGNERAY, a town of France, in the department of the Rhône and Loire; 8 miles W.S.W. of Lyons. VAULT, FORNIx, in Architecture, an arched roof, so contrived, as that the several stones of which it consists, do, by their disposition, suflain each other. Vaults are to be preferred, on many occasions, to soffits, or flat ceilings, as they give a greater rise and elevation; and, besides, are more firm and durable.

The
VAU

The ancients, Salaminus observes, had only three kinds of vaults: the first, the fornix, made cradle-wife; the second, the sestifuddo, tortoise-wife, called by the French cul de four, or oven-wine; the third, the contesa, made shell-wife.

But the moderns subdivide these three sorts into a great many more, to which they give different names, according to their figures and use; some are circular, others elliptical, &c.

The sweeps of some, again, are larger, and others less portions of a sphere: all above hemispheres are called high, or surmounted vaults; all that are less than hemispheres, are low, or unfurthed vaults, &c.

In some, the height is greater than the diameter; in others, it is left: there are others, again, quite flat, only made with haunies; others oven-like, or in form of a cul de four, &c. and others growing wider, as they lengthen, like a trumpet.

Of vaults, some are single, others double, crosy, diagonal, horizontal, ascending, defending, angular, oblique, pendant, &c. There are likewise Gothic vaults, with penentures, &c.

VAULTS, Mother, are those which cover the principal parts of buildings; in contradistinction to the left, or subordinate vaults, which only cover some little part, as a pallated gate, &c.

VAULT, Double, is such an one, as being built over another, to make the exterior decoration range with the interior, leaves a space between the convexity of the one and the concavity of the other: as in the dome of St. Paul's at London, and that of St. Peter's at Rome.

VAULTS with Compartiments, are such whose sweep, or inner face, is enriched with panels of sculpture, separated by platabands: these compartments, are of different figures, according to the vaults, and are usually gilt on a white ground, are made of stucco, or brick vaults; as in the church of St. Peter's at Rome; and with plaster, on timber vaults.

VAULTS, Theory of. A semicircular arch, or vault, standing on two piers, or impost, and all the stones that compose it being cut and placed in such manner, as that their joints, or beds, being prolonged, do all meet in the centre of the vault; it is evident, all the stones must be in form of wedges, i.e. they must be wider and bigger at top than at bottom; by virtue of which they sustain each other, and mutually oppose the effort of their weight, which determines them to fall.

The stone in the middle of the vault, which is perpendicular to the horizon, and is called the key of the vault, is sufficed on each side by the two contiguous stones, just as by two inclined planes; and of consequence, the effort it makes to fall, is not equal to its weight.

But still that effort is greater, as the inclined planes are less inclined; so that if they were infinitely little inclined, i.e. if they were perpendicular to the horizon, as well as the key, it would tend to fall with its whole weight, and would actually fall, but for the mortar.

The second stone, which is on the right or left of the key-stone, is sufficed by a third; which, by virtue of the figure of the vault, is necessarily more inclined to the second, than the second is to the first; and, of consequence, the second, in the effort it makes to fall, employs a less part of its weight than the first.

For the same reason, all the stones, reckoning from the key-stone, employ still a less and less part of their weight to the last; which resting on an horizontal plane, employs no part of its weight; or, which is the same thing, makes no effort to fall; as being entirely supported by the impost.

Now, in vaults, a great point to be aimed at is, that all the several stones make an equal effort in order to fall: to effect this, it is visible, that as each (reckoning from the key to the impost) employs a still less and less part of its whole weight; the first, for instance, only employing one-half; the second, one-third; the third, one-fourth, &c.; there is no other way to make those different parts equal, but by a proportionate augmentation of the whole, i.e. the second stone must be heavier than the first; the third, than the second, &c. to the last; which should be vastly heavier.

M. de la Hire demonstrates what that proportion is, in which the weights of the stones of a semicircular arch must be increased, to be in equilibrio, or to tend with equal forces to fall; which gives the firmest disposition a vault can have.

Before him, architects had no certain rule to conduct themselves by; but did all at random. Reckoning the degrees of the quadrant of the circle from the key-stone to the impost; the extremity of each stone will take up so much the greater arch, as it is farther from the key.

M. de la Hire's rule is, to augment the weight of each stone above that of the key-stone, as much as the tangent of the arch of the stone exceeds the tangent of the arch of half the key. Now, the tangent of the half stone, of necessity, becomes infinite, and of consequence, its weight should be too; but as infinity has no place in practice, the rule amounts to this, that the last stones be loaded as much as possible, that they may the better resist the effort which the vault makes to separate them; which is called the floor, or drift, of the vault.

M. Parent has since determined the curve, or figure, which the extrados, or outside of a vault, whose intrados, or inside, is spheroidal, ought to have, that all the stones may be in equilibrio. See Arch.

VAULT, Key of. See Key and Vousoir.

VAULT, Reins or Fillings-up of, are the sibles which sustain it.

VAULT, Pendantive of a. See Pendantive.

VAULT, Impoll of a, is the stone on which the first vousoir, or arch-stone of the vault, is laid. See Imposts.

VAULT, in the Minope. To vault a hoarse-hole, is to forge it hollow, for horses that have high and round foals; to the end that the shoe, thus hollowed or vaulted, may not bear upon the sole that is higher than the hoof; but after all, this fort of shoe spoils the feet; for the sole, being tenderer than the shoe, affumes the form of the shoe, and becomes every day rounder and rounder. In Mr. Sulley's Complete Horsemans, may be seen the true method of shoeing high and round foals. See Shoe and Shoebing.

VAULT, or Volte. See Volte.

VAULT, Going to the, a term used by sportsmen for a hare's taking the ground like a coney, which the sometimes does.

VAULT, Ls, in Geography, a town of France, in the department of the Yonne; 3 miles W. of Avallon.

VAULX, a town of France, in the department of the Straits of Calais; 4 miles N.E. of Bapaum.

VAUX Malines, a town of France, in the department of the Hore; 12 miles N.E. of Vienne.

VAUNIA, in Ancient Geography, a town of Italy, belonging to the Bechini. Ptolemy.

VAUNING, in Mineralogy. See Van, Vanning, and Tin.

VAUNT', or VANT. See Van.

VAUNT-Lay, among Hunters, a setting of hounds, or beagles, in a readiness where the chase is to pass; and calling them off before the rest of the kennel come up.

VAUQUE-
VAUQUELIN, in Biography. See Ivetaux.
VAUQUELINIA, in Botany, a genus dedicated by M. Correa de Serra, now the Portuguese minister to the United States of America, to the honour of the celebrated French chemist M. Vauquelin, whose discoveries have been extended to the vegetable kingdom. Humboldt and Bonpland, Plantae equinoxiales, fæc. 6. De Theis 478.
We regret that we are furnished with no further account of this genus, nor with any of its characters.

VAUS, in Geography, a river of West Florida, which runs into the St. Mark, N. lat. 30° 10'. W. long. 84° 36'.

VAUVENARGUES, a town of France, in the department of the Mouches of the Rhône; 6 miles E.N.E. of Aix.

VAUVERT, a town of France, in the department of the Gard; 9 miles S. of Nîmes.

VAUVILLE, a small seaport-town of France, in the department of the Channel, on a bay to which it gives name; 9 miles W. of Cherbourg. N. lat. 49° 39'. W. long. 1° 35'.

VAUVILLERS, a town of France, in the department of the Upper Saône; 12 miles N.W. of Luxeuil.

VAUVINCOURT, a town of France, in the department of the Meuse; 5 miles N. of Bar-le-Duc.

VAUX, L.A., a district of Switzerland, in the Pays de Vaud, between Laufanne and Veyvay, which contains the two pleasant little towns of Lutry and Cully, with the villages of St. Saphorin and Corfer. This district is entirely hilly, rising abruptly from the lake; above the vineyards are rich meadows and a continued forest. In the church of St. Saphorin is an ancient Roman mile-stone with an inscription, which contains two circumstances often questioned; viz. that the banks of the lake of Geneva, which border this part of Switzerland, were comprised within a Roman province, even fo early as the time of Claudius, and also that Aventicum was the chief town of this part of Helvetia; for the mile-stones always referred to the capital of the province in which they were placed, and to the distance of St. Saphorin to Avenches is nearly 37,000 paces. The inscription is as follows:

TI. CLAVDIUS. DRUSUS F.
CÆS. AUG. GERM.
PONT. MAX. TRIB. POT. VIL.
IMP. XII. F. P. COS. III.
F. A.
XXXVII.

VAUXHALL GARDENS, a well-known place of public amusement in the parish of Lambeth and county of Surrey, which belonged, in 1615, to Jane, widow of John Vaux, between whose two daughters the estate was divided, and passed through various hands, till both moieties were purchased, about the middle of the last century, by Jonathan Tyers, esq. It does not appear at what time this place was first opened for public resort; but we are led to conclude from a paper in the Spectator (No. 388.), and another in the Connoisseur (No. 68.), that it must have been so appropriated in or before the time of queen Anne. Mr. Tyers, who held the premises on lease many years before he bought the estate, opened the Spring Gardens, as they were then denominated, in 1730, and expended large sums in embellishing them. After his death they fell into the possession of severall proprietors, of whom the principal is Mr. Barratt. These gardens were, till late years, opened every evening during a great part of the summer, for the reception of company; but they are now admitted only three times a week. The entertainments consist of music, vocal and instrumental, illuminations, and fire-works, and other exhibitions. See Lambeth and Tyers.

VAUZ, in Geography, a river of Pennsylvania, on the Susquehanna; 12 miles N.N.W. of Harrisburg.

VAYHINGEN, a town of Wurtemberg, on the Elzt, with a castle. This town had formerly counts of its own; 11 miles N.W. of Stuttgart. N. lat. 48° 58'. E. long. 59° 54'.

VAYLOO, a town of Hindooftan, in Baraimall; 11 miles S.S.W. of Namaul.

VAYPAR, a town of Hindooftan, in the province of Madura; 25 miles E. of Colpetta.

VAYRES, a town of France, in the department of the Gironde; 3 miles S.W. of Libourne.

VAYU, in Hindoo Mythology, is a name of the regent of the winds, more commonly called Purana; see Vayu. Vayu is the Eolus of the East. One of the Puranas is named after him, being called Vayu Purana. (See Purana.) Yah is another of his names.

VAYVODE, or Vaiwode. See Waywode.

VAZABU, in the Matrias Medica, a name by which some authors have called the acorus晋级, or Asiatice sweet-flag.

VAZCUSE, in Geography, a river of Louisiana, which runs into the Missoura, N. lat. 38° 31'. W. long. 94° 5'.

VAZUA, in Ancient Geography, a town of Africa Prætris, between the river Bagradas and the town of TbarBacra, according to Ptolomy.

UBALDI, Guido, in Biography, an eminent mathematician of noble extraction from a branch of the family of Bourbon, fluided under Condamine, and made early as well as rapid proficiency. Mathematics and mechanics were his favourite objects; but in the latter science he published a work, entitled "Mecanicorum Liber, in qua hac continentur:—de Libra, Væcte, Trochlea, Axe in Peritrochio, Cuneo, Cochlea," Venetis, 1615, fol. In this work he reduces all machines to the lever, applying the same principle with advantage to some of the other mechanical powers, and particularly to the pulley and its combinations. He also explained the structure of the scree of Archimedes, and its application to the rife of water, in a treatise "De Cochlea, LIBRI QUARTO," Venet. 1615, fol. He illustrated the principles and practice of perspective more fully and clearly than other preceding writers had done, but with needles prefix by, in his "Perpæctiva, LIBRI sex," Piaur, 1600, fol. His other works, mentioned by Kullmer, are "Guidi Ubaldi c Marchionibus Montes (of the Marquises del Monte) in duo Amichedus Equi ponderantur Libros Paraphraphis, felohis illustrata," Piaur, 1588, fol. "Problematum Albronomiccum Libri septem," Venet. 1528, fol. The time of his birth and also of his death is unknown. Montuella.

UBAMBA, in Geography, a town of Brazil, near the coast of the Atlantic; 80 miles S.W. of Rio Janeiro.

UBARCO, CAFE, a cape on the N.W. coast of the island of Ivoica. N. lat. 30° 18'. E. long. 19° 18'.

UBATUBA, in Geography, a river of Brazil, which runs into the Atlantic, S. lat. 3° 20'.

UBAYE, a river of France, which runs into the Durance, near Embrun.

UBEDA, a city of Spain, in the province of Jaen, containing 20 parishes, 8 convents, and about 2500 inhabitants. In 1235, Ubeda was taken from the Moors; 3 miles E. of Jaen. N. lat. 38° 3'. W. long. 3° 31'.

UBENITZ,
Opposite to St. Ubes, on the narrow strip of land that forms the entrance of the harbour, are the remains of an ancient city, called Troya. Tradition reports that this place was buried in sand; and that the inhabitants removed and built St. Ubes on the opposite side.

UBI, or UBY, an island in the East Indian ocean, in the gulf of Siam, near the coast of Cambodia; about 21 miles in circumference, with plenty of wood and good water. N. lat. 8° 26'. E. long. 105° 56'.

UBIGAU, a town of Saxony; 6 miles N.W. of Liebenwerda. N. lat. 51° 34'. E. long. 12° 20'.

UBII, in Ancient Geography, a people whose first abode was on the other side of the Rhine, being separated from Gaul by the river. Being afterwards pressed by the Suevi, they had recourse to Caesar. Agrrippa baffled the Rhine, according to Dion Cassius, and transported them to the hither bank of the river and established them, with a view to the security of the adjoining frontier of the empire. Under the reign of Claudius, an Agrippine colony was founded among them, and they voluntarily assumed the name of Agrippinenses, as their attachment to the Romans excited the enmity of Civilians. Their territory extended along the Rhine, from the Treveri to the borders of the Gugerni, who had been a branch of the Menapii. The Ubians, on the right bank of the Rhine, were continually harassed by the Sicambri, and in order to avoid the hostilities of such neighbours, they were induced to cross the river. Agrrippa caused them to build a town, which was called "Civitas Ubiorum," in which he planted a Roman colony, denominated "Colonia Agrippina." This town is the present Cologne. The Ubii formed a part of the Germanic body, which they abandoned in order to enter into a league with the Celtic people. This separation of the Ubians is referred to about the thirteenth year before our era. They worshipped the god Mars.

UBIQUISTS, UBIBIANS, or UBIBIANS, formed from ubique, every where, in Ecclesiastical History, a sect of Lutherans, which rove and spread itself in Germany; and whose distinguishing doctrine was, that the body of Jesus Christ is every where, or in every place.

Brenthus, one of the earliest reformers, is said to have first broached this error, in 1563. Luther himself, in his controversy with Zwingius, had thrown out some unpardonable expressions, that seemed to imply a belief of the omnipresence of the body of Christ; but he became sensible afterwards, that this opinion was attended with great difficulties, and particularly that it ought not to be made use of as a proof of Christ's corporal presence in the eucharist. (Luther, Oper. tom. viii. p. 375; ed. Lemm.) However, after the death of Luther, this absurd hypothesis was renewed, and dressed up, in a specious and plausible form, by Brenthus, Chemnitus, and Andreus, who maintained the communication of the properties of Christ's divinity to the human nature.

Melahonius declared against it; maintaining that it introduced, with the Eutychians, a kind of contusion into the two natures of Jesus Christ; and professed, that he would oppose it as long as he lived.

On the other hand, Andreus, Flavius libyces, Schindlin, Otlander, &c. espoused Brenthus's party; and asserted the body of Jesus Christ to be everywhere.

The universities of Leipzig and Wittenberg, and the generality of Protestants, set themselves against this new heresy, but in vain: the Ubibians grew stronger and stronger. Six of their leaders, Andreus, Schnejere, Mifcellus, Chemnitus, Clytrasus, and Corosus, having a meeting in 1576, in the monastery of Berg, they there com-
posed a kind of credo, or formula of faith, called the "Form of Concord"; wherein the ubiquity was established as an article. See Form of Concord.

Mucius, one of those leaders, and the most zealous advocate of the ubiquity, expressly maintains, that the attention of Christ into heaven was nothing more than a ceasing to be visible, and that it is not performed by any physical motion, or change of place: and in 1557 he published a book to prove that it is by no means necessary, that the glorious body of Christ should physically fill up any space. And he declares in a sermon in 1564, that they who teach that Jesus Christ died only as to his human nature, belong to the devil, both body and soul; and that the true doctrine is, that he died as to his human and divine nature. Hospin. Hifior. Sacram. part ii. p. 492. ad ann. 1561. Idem ibid. p. 553. ad ann. 1564. Idem ibid. p. 600. Bayle, art Mucius.

All the Ubiquists, however, are not agreed: some of them, and among the rest the Swedes, hold that Jesus Christ, even during his mortal life, was every where; others maintain, that it is only since his ascension that his body is every where.

G. Hornius only allows Brentius the honour of being the first propagator of ubiquitism; its first inventor, according to him, was John of Wedithala, or Wethphalus, a minister of Hassingham, in 1553.

But according to Hospinian, Wethphalus opposed the opinion concerning the ubiquity advanced by Brentius and Schmidelin. Bayle, art. Wethephalus.

Ubiquist, in the University of Paris, is a term applied to such doctors in theology, as are not restrained to any particular house; either to that of Navarre, or Sorbonne. The Ubiquists are called, simply, doctores in theologia; whereas the others add, de the house of Sorbonne, or Navarre, &c. See Sorbonne.

Ubiquity, Omnipresence; an attribute of the Godhead, whereby he is always intimately present to all things; gives the effe to all things; and knows, prefers, and does all in all things.

For since God cannot be said to exsit in all places, as placed therein, (because, then, he would need something to his existience, viz. place; and would have extension, parts, &c.) he must be conceived to be every where, or in all things, as a first, universal, efficient cause, in all his effects.

If God is present, therefore, to all his creatures, as a pure act, or an exercise of an active virtue, which knows, prefers, governs, &c. every thing. Nor are even finite minds prefect otherwise than by operation. See God.

Ubiquity of the King. See King.

Ubirre, in Ichthyology, a name given by some to the anguilla marina, or small sea-eel.

Ubium, in Botany, altered by Rumphius, Herb. Amboin. book 9. 346, from the Malay name Ubik, a synonym of some species of Dioscorea; see that article. Forster declares all the kinds of Ubium, mentioned by Rumphius, to belong to D. alata. These differ chiefly in the shape of the roots, and in the stems being furnished or not with fleshy buds, or bulbs, of different forms. These roots constitute one of the most important articles of food, in the remote islands of India and the South Seas.

Ubn, in Geography, a town of Walachia; 10 miles N. of Viddin.

Uboa, a town on the west coast of the island of Luçon. N. lat. 16° 57′. E. long. 120° 48′.

Ubraye, a town of France, in the department of the Lower Alps; 9 miles N.E. of Caffelane.

UBRILEN, a town of the Arabian Ira; 5 miles S.E. of Baffora.

UBRIX, in Ancient Geography, a town of Africa, on the coast of Libya. Ptolemy.

UCA, a town of Asia, in the interior of Media. Ptolemy.

UCANDO, in Geography, a town of Portugal, in the province of Beira; 2 miles N. of Lamego.

UCAYALE, Ucaial, or Ycayale, a river of South America, formed by the union of the Apurimac and Ene, in S. lat. 10° 50′. It pursues a northerly course to S. lat. 4° 15′, where it joins the Maranon, near St. Joachim de Omágues, and then takes the name of the Amazonas. See Maranon.

UCENA, in Ancient Geography, a town of Asia, in Galatia, belonging to the Trochmi. Ptolemy.

UCELI, a people placed by the inscriptions on the trophy of the Alps, mentioned by Pliny, near the Medulli and the Caturiges, and supposely by Sanlon to be the fame with the Siconii or Iconii, mentioned by Strabo.

UCETERA, a town of Gallia Narbonensis.—Alfo, a town of Gallia Tranpadana. Strabo.

UCHALIGES, a people of Africa, in Libya Interior. Ptolemy.

UCHENDGE, in Geography, a town of the principality of Georgiæ, and chief place of a district, situated to the east of Tepit. In 1395, this town was taken by Timur Ben, and the whole garrifon put to the sword.

UCHINCHIR, one of the small Kurile islands, in the North Pacific ocean. N. lat. 48° 30′. E. long. 153° 44′.

UCHKILISSA, a town of Persia Armenia; 18 miles N.W. of Erivan.

UCHT, a river of Brandenburg, which runs into the Aland, near Olterburg.

UCHTILHASEN, a town of the duchy of Wurz- burg; 6 miles E. of Schweinfurt.

UCIBI, in Ancient Geography, a town of Africa Propria, in Numidia Nova. Ptolemy.

UCIMATH, a town of Africa, in Libya Interior, upon the northern bank of the river Gird. Ptolemy.

UCK, in Geography, a river of Pomerania, which empties itself into the Friiche-Haff, 1 mile N. of Ucker- munde.

UCK Mark. See Brandenburg.

UCKER, see a confiderable lake of Brandenburg, in the Ucker Mark, situated to the north of Prenzlau.

UCKERMUNDE, a town of Anterior Pomerania, situated on the river Ucker, near its entrance into the Friiche-Haff. This town was surrounded with walls in 1190. In the 17th century it suffered greatly by sieges, and the vicissitudes of war; and in 1713, was sacked by the Russians. It has good fisheries, pastures, and woods; 29 miles N.N.W. of Old Steettin. N. lat. 53° 48′. E. long. 13° 57′.

UCKEWALLISTS, in Ecclesiastical History, a sect of rigid Anabaptifts, so called after its founder Uke Walleis, a native of Friesland. This fectary not only exhorted his followers to maintain the primitive and auterie doctrine of Menno, but took it into his head to propagate, in connection with one John Leus, in 1637, a fegular opinion concerning the salvation of the human, and the reft of Christ's murderers; alleging, that the period of time, which extended from the birth of Christ to the defection of the Holy Ghost, and was, as it were, the diftinctive term that separated the Jew from the Chriffian defpiation, was a time of profound ignorance, during which the Jews were deifie both of light and divine succour; and that, confi
quently, the sins and enormities, that were committed during this interval, were in a great measure executable, and could not merit the fevered displays of the divine justice. This idle fiction met with no indulgence either from the Monnenetos, who excluded its inventor from their communion, or from the magistrates of Groningen, who banished him from the city. In East Friesland he drew after him a considerable number of disciples, whose defendants still furbish in the neighbourhood of Groningen, Friesland, and also in Lithuania and Prussia, and have their own religious assemblies, separate from those of the other Monnenites. They re-baptize all who leave other Christian churches to embrace their communion: they studiously avoid every appearance of elegance or ornament; suffer their bristles to grow to an uncommon length, and their hair to lie uncombed over their shoulders: their countenances are marked with melancholy; and their houses only adapted to answer the demands of necessity. Their inspectors or bishops, whom they distinguish from the ministers whose office is to teach, are chosen by an assembly composed of all the congregations of the sect. The ceremony of washing the feet of strangers is considered by them as a rite of divine institution. They carefully avoid even the aspect of learning and science, and thus prevent all attempts to alter or modify their religious discipline. Moheim's Eccl. Hist. vol. v. 8vo.

UCLES, in Geography, a town of Spain, in New Castile. In 1108, a battle was fought near this place between the Christians and the Moors, in which the former were defeated with great loss; 20 miles S.W. of Huete.

UCO, a town of Chili; 9 miles E.S.E. of St. Yago.

UCRIA, a town of Sicily, in the valley of Demona; 8 miles W.S.W. of Patti.

Gen. Ch. Cal. Perianth superior, of one leaf, short, cup-shaped, with five angles, and five cleft, acute teeth, permanent. Cor. of one petal, tubular; tube extremely long and slender, cylindrical, pellucid; limb bell-shaped, with five rather short, ovate, acute, equal, slightly spreading, marginal segments. Stam. Filaments five, very short, inserted into the limb between the segments; anthers incumbent, oblong, pointed, of two cells. Pet. Germin inferior, elliptical; style the length of the tube of the corolla, thread-shaped; swelling and hairy at the top; stigma of two rounded lobes. Peric. Berry elliptical, fleshy, of two cells, crowned by the permanent calyx. Seeds numerous, roundish, inserted into the middle of the partition at each side, and surrounded with viscid pulp.

1. U. speciosa. Willd. n. 1. (Tocoyena longiflora; Aubl. t. 50.)—Native of woods in Guiana, bearing flowers as well as fruit in August. Stem shruny, simple, about three feet high, obtusely quadrangular, leafy. Leaves opposite, falcate, fifteen inches long; lanceolate, acute, entire, smooth, contracted at the base, with one rib and many transverse veins. Stipulas in pairs, intrafollicose, ovate. Flowers about fourteen, crowded at the top of the stem, sessile, opposite, erect, very fragrant, white, with a yellow tube, nine inches and a half long, the thickens of a goose-quill. Calyx very small. Berry yellow, an inch in length.

This plant comes very near to Gardenia, or at least to Thunberg's Rothmannia. (See Gardenia.) We do not profess to have had sufficient opportunities of comparing them and their allies, to form an accurate judgment. Willdenow has changed the specific name without any authority or reason.

UCUBIS, in Ancient Geography, a town of Spain, in Bottica.

UDA, in Geography, a river of Russia, which runs into the Velika, 12 miles N.W. of Ongoka, in the government of Piltov.—Also, a river of Russia, which joins the Tchiuna, N. lat. 55° 50'; E. long. 99° 22'.—Also, a river of Russia, which runs into the Selenga, near Verch Udink.—Also, a river of Russia, which runs into the sea of Ochotch, N. lat. 55° 15'. E. long. 178° 44'.

UDACENSES, in Ancient Geography, mountains of Asia, in Corduena, south of the lake Arliffa, lat. 37° 30'.

UDAL. See Odial.

UDASSA, in Geography, a town of Hindooftan, in Goondwana; 12 miles N.W. of Nagpooor.

UDAWANTANAGUR, a town of Hindooftan, in Bahar; 5 miles S.S.W. of Arrah.

UDDALA, in Hindoo Mythology, is the name sometimes given to a theologian, who is said to be the son of Aruna, the charioter of the sun. He is not often read of. Respecting his parent, who corresponds with the Aurora of western fable, notice will be found under our article Surya, the common name of the Hindoo Theburs.

In the theogonies of the Puranas, when describing the process of churning the ocean, as mentioned in our article Kurumavatara, a goddess, named Jyefta, was produced. She is deemed the goddesses of poverty and misfortune, and having rose from the sea earlier than Lakthmi, the goddess of riches and fortune, is called her elder sister. Vithnu, enamoured of the latter, wished to elope her; but she objected, saying her elder sister, agreeably to the injunctions of the Vedas, ought to be married first. And this we may remark, in passing, is a rule in force at this day, though not invariably observed. Vithnu, after much difficulty, prevailed on Uddalaka the Rishi, who was unmarried, to take the undelirable damsel to wife; and Sagara, her father, sealed the nuptial ceremony by pouring water into the hands of the Rishi. (See Sagara.) Jyefta, like Lakthmi, is called the daughter of the ocean, and is celebrated as being ever faithful to her comfort. She is sometimes called Srefta.

Under the article Rishi will be found an account of the holy men so designated. One of them taking the goddesses of poverty to wife, means, we may suppose, the usual profession of poverty by pious perfons. It was no small sacrifice of comfort to be linked to such a rib: for Jyefta is described to have arisen in black garments, with yellow hair, red eyes, wanting many teeth, those remaining of repelling appearance, her tongue lolling out of her mouth, potbellied, &c. &c.; so that gods and demons were amazed at the sight of such a figure. Such a one is described, from an image in the East India House, in our article Kali. Her younger sister, on the contrary, is described as superlatively fascinating, but fickle; being a personification of Fortune.

UDDEN, in Geography, a town of Arabia, in the province of Yemen; 44 miles E.S.E. of Zebid. N. lat. 15° 5'. E. long. 43° 50'.

UDDE,
UDDER, in Rural Economy, a term applied to the glandular organ which is destined for the preparation and secretion of the milk in cows, mares, ewes, fows, or any other kinds of domestic animals, and which is often much subject to disease.

It is to be noticed, that the udders of young cows which are in a high condition, are sometimes very greatly swollen and inflamed for several days before they calve; in which cases, it is mostly proper to milk them frequently in repetition, and alternately to anoint the diffused parts, in some severe infances, with a fururine cooling ointment, and brandy, or some other quickly evaporating spirit; as, by such means, these swellings are often speedily removed, without much danger or inconvenience. But, besides these sorts of swellings, the udders of cows are liable to injuries, which are often of a more serious consequence, as from falls, blows, the wounds of sharp instruments, or such as are pointed, and the violent hacking of calves, as well as from the injudicious or rough treatment of harsh and inexperienced milkers. In all such cases, while the inflammation in the glands remains in a hard and indolent state, the parts so affected should be repeatedly anointed in the course of the day with some gentle cooling substanct, such as fresh lizard, or with a solution consisting of one ounce of Caltice soap, dissolved in a pint, and a half of new milk, over a moderate fire, constantly stirring it until it becomes thoroughly mixed and incorporated. An ointment, too, prepared from the juice of the leaves of the common thorn-apple, by mixing it with fresh hog’s-lard, is said by some to be an excellent application in cases of this nature. Such tumours may likewise, in many instances, be anointed with a little of a composition, consisting of camphor dissolved in spirit and blue ointment, with great benefit; and about half a dram of calomel may be given in a hornful of treacle and warm beer, three or four mornings together, if the swelling should continue to increase. Where, however, the udder and teats are considerably inflamed and swelled, other internal remedies may be had recourse to; for which purpose, it has been recommended to mix four ounces of nitre with one pound of common salt, and to give two table spoonfuls of the powder in a gallon of thin water-gruel every three hours. But in cases where the affection, in such instances, should have made, from neglect, such progress as to displace large hardish tumours in the parts, fomentations of the sort given below may often be applied with advantage. Boil in a sufficient quantity of water one handful of the leaves of common hemlock, the fame quantity of the dwarf or round-leaved mallow, and an equal proportion of common melilot; and diligentlly apply the liquid, by means of cloths wrung out of it, to the part or parts, as warm as the beast can bear it. As soon as the tumour or tumours, in this case, bursts or opens, the wound should be well and properly cleaned, and then covered with a pledge of lint, and a platter of common cerate or balacim laid over all.

The remedy directed below, it is said, has been employed with great success in very obstinate cases of ulcerated cattle udders: one ounce of gum ammoniacum, the same quantities each of gum galbanum, Caltice soap, and extract of hemlock; reduce the gums into powder, and form them with the soap and extract into eight small balls, one of which is to be given to the beast every night and morning. In cases where the teats only are sore, they may first be washed well with clean warm soap-lads, and then rubbed with an ointment, composed of finely powdered cerule or white lead, which has previously been tinctured with brandy, and well mixed and united with a proper quantity of elder ointment or goose-grace.

In the case of sheep too, these parts are often much affected, when the lambs are yeaned in the ewes, the lactiferous ducts in the udders of which are liable to become attacked with various obstructions, which are the consequence of hard tumours or swellings being formed, which are accompanied with inflammation, and which, if not speedily relieved, will terminate in mortification, not unfrequently in the course of twenty-four hours. As soon as such swellings or tumours are discovered, the wool should be shorn off closely in a careful manner, and the part affected be frequently wetted and rubbed well with camphorated spirit of wine. If, however, suppuration should ensue, the part should be laid open by a strong lancet or sharp knife, and the matter be discharged, when a pledge of lint should be laid over the part, and secured by a plaster spread with some soft ointment, or the common cerate rubbed with a little oil. Ewes, when thus affected, should be kept separate from the rest of the flock, and though one of the nipples may be lost, they may be allowed to fuckle their lambs; but in cases where both are affected, there is, of course, no alternative but that of fattening them off for sale, and to bring up their lambs by hand in the best manner possible.

The udders and nipples of ewes are likewise very apt to be irritated, chafed, and fretted, by which the lambs are prevented from being let suck in a proper and ready manner; consequently, in all such cases, the parts so affected should be kept as cool as possible, and be well washed with a weak solution of white vitriol in rain-water, or be anointed with some mild softening ointment, such as that of elder, or common cerate softened with oil, once or twice in the day; care being taken to keep them well removed by the use of warm water and a little soft soap, before the lambs be again admitted to them for suckling.

The diseased of the udders, in the other sorts of domestic animals, are, for the most part, to be treated in a similar manner, according as the nature of them may be: always having the parts carefully cleaned, before the young are suckled.

UDDER-Locking, a term used in the management of sheep, to signify the practice of clearing away the locks of wool from about the udders, and other parts, where the lambs suck, in ewes. Some sheep-farmers have a very high opinion of the necessity and utility of this custom, while others as strongly condemn it, and consider it to be quite unnecessary, as well as dangerous and hurtful both to the ewes and the lambs. It may, however, be useful in different cases and circumstances. The former, or those in favour of the practice, recommend that, immediately before the ewes begin to drop their lambs, they should be carefully driven into the yards, folds, or pens, and have a small part of the locky wool pulled off from about their udders, in order to give the lambs more easy and ready access to the teats or nipples, by which they come forward faster, and succeed better. But the latter, or those who object to the custom, think that they have seen instances where it occasioned not only the death of nearly one-twentieth part of the ewes, but that many of those which survived it, lambed dead lambs at the danger and hazard of their own lives. They suppose that there is naturally a sufficient space left bare about these parts, so as to enable the young lambs to find the dugs or nipples; and that the uncovering more, or a larger extent of parts, serves only to starve and expel the ewes in the most tender and delicate parts; as, although they have been engaged among sheep the whole of their lives, they have never seen a single lamb die from the want of its dam or mother being udder-locked, even though the
may have been ever so young, or ever so rough in such parts; nor have they ever met with any persons who could be certain that they had seen any. How far some breeds of sheep, as those of the Cheviot, may have their lambs more readily or more easily killed or destroyed in this way, or whether it may not be owing to the shape of the udders in their dams, which being more full and expoded in such parts, is not by any means well known; but far less injury or exposure, in this or in any other way, will make that breed of sheep lamb dead lambs, it is said, than in the forest, or probably some other breeds.

But though this practice may often be found prejudicial in the more northern parts of the kingdom, in the southern sheep districts it may not unfrequently be had recourse to with very considerable utility and advantage in different respects.

UDDEVALLA, in Geography, a sea-port town of Sweden, in the province of Halland, with a strong fort and convenient harbour. The inhabitants carry on a considerable trade in iron, planks, and herrings; their number is about 9000; 205 miles W.S.W. of Stockholm. N. lat. 58° 21'. E. long. 11° 45'.

UDEBOEDE, a town of the island of Ceylon; 60 miles S. of Candi.

UDEGHERRY, a town of Hindoostan, in the Carnatic; 43 miles N.W. of Nellore. N. lat. 14° 43'. E. long. 79° 16'.

UDÉM, a town of France, in the department of the Aisne; 7 miles S.S.E. of Cleves.

UDERFONDA, a town of Hindoostan, in Mysoor; 20 miles N.W. of Amuntpour.

UDERWANGEN, a town of Prussia, in Natangen; 12 miles S.S.E. of Königsberg.

UDI, a town of Egypt; 10 miles N. of Aitfich.

UDJARMA, a town of the principality of Georgia, in the province of Kakhet; 24 miles E. of Tiflis.

UDICA denotes the projecting part of a barges stern, on which its name, &c. is printed.

UDINA, or UDINE, in Geography, a town of Italy, and capital of Friuli; to which, on the decline of Acquileia, the patriarch removed his seat. It has several churches, convents, and hospitals, a college for the study of law, and a military academy: and it is said to contain between 17,000 and 18,000 inhabitants; 35 miles N.W. of Trieste. N. lat. 46° 10'. E. long. 13° 14'.

UDINE, Giovanni da, in Biography, was the cousin of an assistant of Raffaello in the works of the Vatican, whose real name was Nanni. His family resided at Udine, (where he was born in 1454,) and had there followed the occupation of embroiderers with so much excellence, as at length almost to have lost their own name in that of Ricamatori, by which Vafiari often calls him. His father, become rich, amased himself with hunting; and his son Giovanni found his sport, at a very early period of his life, in drawing the animals, birds, &c. brought him from the chase. This indication of taste for painting was encouraged, and the youth was placed under the tuition of Giorgione, at Venice, with whom he acquired a knowledge of colour and chiaro-scuro. About the time of the death of Giorgione he went to Rome, and being furnished by his protector, the patriarch Grimani, with letters to count Baldassare Cattiglione, he was introduced to Raffaello, who admitted him into his school, and employed him in painting the grotesque and ornamental accessories of his larger works. The imagination of this master Raffaello, and of himself, was led to the introduction of this species of ornament, by the discovery of the painted chambers in the baths of Titus, then recently opened, when Giovanni was employed in making designs of the beautiful ornaments in ituco found there, and thence denominated grotesque. In pursuing these studies, he discovered the composition of the Italian inventions or rather in which they were painted; and with the same materials he, by order of Raffaello, prepared the walls and ceilings of the Loggie, and painted upon it the beautiful series of ornamental combinations of flowers, fruit, animals, vases, &c. since then so much employed in adorning the dwellings of the rich and great. This part of the work was entirely entrusted to Giovanni da Udine, under whose directions a number of ingenious young men were employed; and the taste and ability, the freedom and truth, without minuteness, with which the whole is managed, has ever since been a constant subject of praise and admiration. After the death of Raffaello, he was employed by Clement VII., in conjunction with Perino del Vaga, to ornament that part of the Vatican called the Torre di Borgia. When he was compelled to leave Rome by the sickness of that city, he was employed for a time at his native place, and afterwards engaged at Florence in adorning the palace of the Medici; and returning to Rome in the pontificate of Pius IV., left in various places there mementos of his admirable ingenuity. He died there, at the age of seventy, in 1564, and had the honour to be buried in the church of La Rotonda, (the Pantheon,) next the tomb of his renowned master.

UDINE, Martino da, called Pellegrino di San Danielo, was born at the castle of San Danielo, near Udine, about the year 1480, and was a disciple of Giovanni Bellini. He pursued the style of that master in the many religious subjects he treated for altar-pieces at Udine and his native place, where his works are principally to be found; though it is said, in addition to his fame, that something of Giorgione's breadth may be discovered in his latter productions. He died about 1514.

UDINSK, Nizhni, in Geography, a town of Russia, ia the government of Irkukh, situated on the river Uda; 260 miles N.W. of Irkukh. N. lat. 54° 15'. E. long. 98° 50'.

UDINSK, Vercbein, a town of Russia, in the government of Irkukh, on the Selenga; 88 miles E. of Irkukh. N. lat. 51° 20'. E. long. 107° 20'.

UDINSKA, a town of Russia, in the government of Irkukh, at the confluence of the Uda and the Angara; 140 miles W.N.W. of Irkukh. N. lat. 54° 12'. E. long. 107° 1'.

UDINSKA, Now, a town of Russia, in the government of Irkukh, on the Uda; 24 miles S.E. of Udinsk.

UDITTA, in Antiqu Geography, a town of Africa Pro peers, between the Two Syrtis. Ptolemy.

UDNON, in Botany, the name by which Theophrasus and Dioscorides have called the truffle commonly used at table in their times; but we find that they were not acquainted with a better kind of truffle, which we cultivate at present.

This smooth reddish-coated truffle is common in Italy at this time, and is esteemed of no value, and called the wild truffle: the fort that is eaten there, and in all other parts of Europe, is the blackish and rough-coated kind. In Africa they have a yet finer kind than ours: it has a white coat, and is of the most delicious flavour. The Greeks were also acquainted with this, and denominated it Cyrena, as they did almost all the things they had from Africa; they also gave it the name autt.

UDO, in the Materia Medica, a name given by the Portugese to the lignum aloes.

It seems only a corruption of the monosyllable sal, by which...
which the Arabian physicians have called that drug; and even this as possibly was only a construction of the orthography of the word *bead*; which seems to have been the original name of this drug among the Arabs.

We do in *Geography*, a town of Japan, in the island of Nippon; 60 miles W. N. W. of Jedo.—Also, a town of Japan, in the island of Ximo. N. lat. 32° 30'. E. long. 132° 30'.

*Udorn*, in *Ancient Geography*, a river of Aiasic Sarmatia; the mouth of which, according to Ptolemy, was in the Caspian sea, between that of Abontas and that of Rhia.

*Udrigill Head*, in Geography, a cape of Scotland, on the W. coast of the county of Ross. N. lat. 57° 54'. W. long. 5° 31'.

*Udssi*, a town of Japan, in the island of Nippon; 15 miles S. W. of Meaco.

*Udskoi*, a town of Ruffia, in the government of Irkutsk, on the Uda; 1100 miles E. N. E. of Irkutsk. N. lat. 55° 16'. E. long. 135° 50'.

*Udstein*, a small island near the coast of Norway; 9 miles N. W. of Stavanger.

*Uduar*, a town of the island of Ceylon; 26 miles S. E. of Galle.

*Udvarhely*, a town of Transylvania; 22 miles N. E. of Scheburg. N. lat. 46° 30'. E. long. 24° 54'.

*Udumnaevskoi*, a fort of Ruffia, in the government of Irkutsk; 88 miles S. W. of Nertchinok.

*Udura*, in *Ancient Geography*, a town of Hifpania Citerior, belonging to the Taccatani. Ptolemy.

*Vea*, in *Geography*, a town of Persia, in the province of Segeltan; 52 miles N. of Zareng.

*Veadar*, in *Chronology*, the thirtieth month of the Jewish ecclesiastical year, answering commonly to our March: this month was intercalated, to prevent the beginning of Nisan from being removed to the end of February.

*Veagues*, in *Geography*, a town of France, in the department of the Cher; 6 miles S. W. of Sancerre.

*Veal Town*, a town of New Jersey; 14 miles N. N. W. of New Brunswick.

*Veas*, a town of Spain, in the province of Seville, on the Oder; 8 miles N. N. E. of Gibralate.

*Veascium*, in *Ancient Geography*, a town of Italy, allied to the Romans; it was attacked by the Gauls on their departure from Rome, but they were surprised and routed by Camillus. Plutarch says, that the Gauls, on leaving Rome, encamped eight miles from this town in Latium.

*Vebron*, in *Geography*, a town of France, in the department of the Lozere; 6 miles S. of Florac.

*Vecchi, Orazio*, in *Biography*, born at Milan, and many years maestro di cappella at Mantua, gained great reputation, not only as an able musician, but a poet. His numerous canzonets for three and four voices, published at Milan and Venice, from 1580 to 1613, were reprinted and sung all over Europe. Our countryman, Peacham, who had received instructions in music from this composer, during his residence in Italy, speaks of him in the following manner: "I bring you now mine other, Horatio Vecchi, of Modena, who, beside goodnights of airs, was most pleasing of all other for his concept and variety, wherewith all his works are singularly beautiful, as well his madrigals of five and six parts, as those his canzonets, printed at Norimberge." (Complete Gentleman, p. 102.) He then infances and points out the beauties of several of his compositions, that were most in favour during that time. Besides secular music, Vecchi composed two books of sacred songs, in five, fix, seven, and eight parts; masses of five and eight voices, and four-part laments.

Vecchi has been erroneously suppos'd by many of his countrymen the inventor of the burletta, or comic opera in Italy; and it was the opinion of the learned Muratori (La Perfetta Poetia, lib. iii. cap. 4.), that a musical drama or farce, called Anfpamaro, written and set by the celebrated Orazio Vecchi, and acted and printed at Venice, 1597, was the origin of the Opera Bufia; which fee.

*Vecchia*, Pietro, born at Venice in 1605, was a painter, educated in the school of Paduanos, but more an imitator of Giorgione and Pordenone; and some of his pictures have been mistaken for works of those masters. Sandarct relates a story of his having been deceived by a picture of Vecchia, which he mistook for one by Giorgione. From this talent of imitating others, the doge and senate of Venice employed him to copy the ancient works in mosaic which are preferred in the church of St. Marc. And in that church are also two original and very able pictures by him, representing the Crucifixion, and Christ driving the money-changers from the temple. His colouring is rich and warm, and his execution free and full, but sometimes apt to be incorrect. He died in 1678, aged seventy-three.

*Vecelli* Titiano. See Titian.

*Vecelli, Orazio*, son of Titian, born at Venice in 1540, practised the art of painting under his father's tuition, but became distinguished only as a painter of portraits, some of which were esteemed as little inferior to those of his father. He died in the same year with his father, 1576.

*Vecelli, Marco*, called Marco da Tiziano, was the nephew and disciple of Titian, and born at Venice in 1545. He appears to have been regarded by his great instructor with peculiar favour, and certainly his talent gave him the fairest claim to such distinction; for he approached the nearer to Titian, both in colour and composition, of all his discipiles, and has left several original works, very deservedly esteemed, in the Palazzo di San Marco. He also executed several considerable works for the churches in Venice, Treviso, and in the Friuli. He died in 1611, leaving a son, known by the name of Il Tizianello, who obtained much repute by his paintings, but they are in a loose and mannered style: his bell productions are his portraits.

*Vechn*, in *Geography*, a river which rises in the biform of Munster, about six miles N. E. of Coesfeld, crosses Bentheim and Overell, and runs into the Zuyder See at Gelmnyden.—Also, a river which passes by Utrecht, and runs into the Zuyder See at Muyden.

*Vechta*, a town and fortress of Germany, in the biform of Munster; 60 miles N. E. of Munster. N. lat. 52° 43'. E. long. 8° 18'.

*Vecs*, a town of Transylvania; 16 miles E. S. E. of Bittriz.

*Vectis*, in *Ancient Geography*, an island of the British ocean, S. of the Portus Magnus, or Great Haven, according to Ptolemy and Pliny.

*Velis*, in *Mechanics*, one of the powers, more usually called the lever; which fee.

*Veltis*, Heterodromus. See Heterodromus.

*Vector*, in *Astronomy*, a line supposed to be drawn from any planet moving round a centre, or the focus of an ellipse, to that centre, or focus.

This, by some writers of the new astronomy, is called vector, or radius vector, because it is that line by which the planet

---

"and"
VEDA.

plane seems to be carried round its centre; and with which it describes areas proportionate to the times.

VEDA, the name by which the Hindoos designate the collective body of their scripture. They enumerate eighteen parts of true knowledge, as follow: four Vedas, four Upavedas, six Angas, and four Upangas. The prefixtre as inferred a work deduced from its principal; like our sub, implying inferiority.

The first four, according to a native writer, quoted by Sir W. Jones, are the immortal Vedas, evidently revealed by God, which are entitled, in one compound word, Rig-yaajfamambarva; or, in separtate words, Rig, Yajura, Saman, and Atravah. The Rigveda consists of five sections; the Yajurveda, of eighty-six; the Samaveda, of a thousand; and the Atravahveda, of nine; with eleven hundred jachas, or branches, in various divisions and subdivisions. The Vedas in truth are infinite; but were reduced by Vyasa to this number and order. The principal part of them is that which explains the duties of man in a methodical arrangement; and in the fourth is a system of divine ordinances.

From these are deduced the four Upavedas; viz. Ayuh, Gandharva, Danuhi, and Sthapatya. The first of which was delivered to mankind by Brahma, Indra, Dhanwantari, and five other deities; and comprises the theories of physicians and medicines, with the practical methods of curing diseases. The second, on music, was invented and explained by Bharata: it is chiefly useful in raising the mind by devotion to the felicity of the divine nature. The third Upaveda was composed by Viphimitra, on the fabrication and use of arms, and implements handled in war by the tribe of Kikletiya. Vifwakarma revealed the fourth, in various treatises on forty-four mechanical arts, for the improvement of such as exercise them. Of the perfonages named above, viz. Brahma, Indra, Viphimitra, Viphwantra, and Vyasa, see under these words respectively. Of Dhanwantari, some mention is made under our article KURNAVATARA.

The fix Angas, or bodies of learning, are also, according to the same native authority, derived from the same source. We omit their names and contents: their subjects chiefly are, 1. Of the pronunciation of vocal sounds. 2. Detail of religious acts and ceremonies. 3. Grammar. 4. Proody. 5. Aironomy. 6. On the signification of difficult words and phrases in the Vedas.

Lastly, continues the same author, there are four Upangas, called Purana, Nyaya, Mimansa, and Dhermafastra. (See PURANA, NYAYA, and MIMANSA.) Eighteen Puranas were composed by Vyasa, for the instruction and entertainment of mankind in general. Nyaya is a collection of treatises in two parts, on metaphysics, logic, philosophy, &c. Mimansa is similarly divided into two parts; the latter, abounding in questions on the divine nature, and other sublime speculations, was composed by Vyasa in four chapters and fifteen sections. It may be considered as the spring of all the Angas; it expoes the heretical opinions of sophists; and, in a manner suited to the comprehension of adepts, it treats on the true nature of Ganea, Bhaskara or the Sun, Nalakantha, Lakhimi, and other forms of One Divine Being. Of Ganea, the god of prudence and sagacity, see under POLEBAR. Bhaskara is a name of Surya. Nalakantha is a name of Siva, the name as Shukakooda. Lakhimi is the consort of Vichnu.

The body of law, called Smrist, consists of eighteen books, &c. delivered for the instruction of the human species by Menu, and other sacred perfonages. As to

ethics, the Vedas contain all that relates to the duties of kings, the Puranas, what belong to the relation of husband and wife; and the duties of friendship and society (which complete the triple division) are taught succinctly in both. This double division of Angas and Upangas may be considered as denoting the double benefit arising from them in theory and practice.

To the above native account of the Vedas, Sir W. Jones adds an ingenious commentary. He says that the Vedas consist of three kandas, or general heads; viz. Karma, Jnyana, and Upana; or works, faith, and worship. To the first of which, the author of the Vidyadara, or View of Learning, a rare Sanscrit book, wisely gives the preference; as Menu himself prefers universal benevolence to the ceremonies of religion.

After all, continues this instructive writer, the books on divine knowledge, called Veda, or what is known, and Sruti, or what has been heard from revelation, are still supposded to be very numerous; and the four here mentioned are thought to have been selected containing all the information necessary for man. It must not be omitted, that the commentaries on the Hindoo scriptures, among which that of Vaidhita (see VASISHTHA) seems to be the most excellent, are innumerable.

From the Vedas are immediately deduced the practical arts of chirurgery and medicine, music and dancing; archery, which compries the whole art of war; and architecture, under which the system of mechanical arts is introduced.

Next in order to these are the fix Vedagas; three of which belong to grammar; one relates to religious ceremonies; a fifth, to the whole compass of mathematics; and the sixth, to the explanation of obscure words or phrases in the Vedas. Subordinate to these Angas, though the reason of the arrangement is not obvious, are the series of sacred poems (see PURANA), the body of law, and the fix philosophical faltras or hitakas. See PHILOSOPHY OF THE HINDOOS, AND SHASTHA.

In the commentary whence we quote parts of this article, Sir William Jones gives some of the reasons that induced him and Mr. Wilkins to believe, notwithstanding the mythological fable of Brahma's four mouths, each of which uttered a Veda, that the fourth, or Atharvaha, was written or collected after the other three; but Mr. Colebrooke, in the fifth volume of the Asiatic Researches, after noticing some texts and arguments on which that belief might be reasonably grounded, gives his own reasons and proofs in support of a contrary opinion. He thinks it probable that some portion at least of the Atharvaha, is as ancient as the compilation of the three others; and its name, like theirs, is anterior to Vyasa's arrangement of them; but the fame, he adds, must be admitted of the portion called Itahafa and Purana, which constitute a fifth Veda, as the Atharvaha does a fourth.

The Hindoos believe that the original Veda was revealed by Brahma, and to have been preferred by tradition until it was arranged in its present form by a sage, who hence obtained the name of Vyasa, or the compiler; or Vedavyasa, that is, compiler of the Vedas. He distributed the Hindoo scripture into four parts, as already enumerated; each bearing the common denomination of Veda.

With the Hindoos it is an article of their creed, that the Vedas were composed by no human author. It must be understood, therefore, that in affirming the primeval existence of their scripture, they deny these works to be the original composition of the editor (Vyasa), but believe them to have been gradually revealed to inspired writers.
VEDA.

It appeared to Mr. Colebrooke from several other passages, and from the received opinion of the Hindoos themselves, that the Rich, Yajush, and Saman, are the three principal portions of the Veda; and the Atharvava is commonly admitted as a fourth; and that divers mythological poems, entitled Itahafa and Purana, are reckoned a supplement to the scripture, and as such constitute a fifth Veda.

The Vedas are a compilation of prayers, called Mantra; with a collection of precepts and maxims, entitled Brahmana: from which last portion, that called Upanishad is extracted. The prayers are properly the Veda, and apparently preceded the Brahmana. Each Veda consists thus of two parts, the Mantras and the Brahmanas; or prayers and precepts. The complete collection of the hymns, prayers, and invocations belonging to one Veda, is called its Sanhita; every other portion of Indian scripture is included under the general head of divinity (Brahmana): this comprises precepts, which inculcate religious duties; maxims, which explain those precepts; and arguments, which relate to theology. But in the present arrangement of the Vedas, the portion which contains passages called Brahmana, includes many which are strictly prayers, or Mantras. The theology of the Indian scripture, comprehending the argumentative portion entitled Vedantas, is contained in the texts denominated Upanishads; some of which are portions of the Brahmana, properly so called: others are found only in a detached form; and one is a part of a Sanhita.

Prayers, employed at solemn rites, called Yajnya, have been placed in the three first Vedas: those in prose are named Yajush; such as are in metre are designated Rich; and some which are intended to be chanted are called Saman; and those names, as distinguishing different portions of the Vedas, are anterior to their separation in Vyasa's compilation. But the Atharvava, not being used at the religious ceremonies above-mentioned, and containing prayers employed at libations, at rites conciliating the deities, and as imprecations on enemies, is essentially different from the other Vedas. This is adduced by Mr. Colebrooke as the true reason why the three first Vedas are often mentioned without any notice of the fourth; which must be sought, he says, not in their different origin and antiquity, but in the difference of their use and purport. The fourth, or Atharvava, is known to contain many forms of imprecation for the destruction of enemies. These are called Mantra (see that article), but it must not be inferred that such is the chief subject of that Veda; for it contains also a great number of prayers for safety, and for the averting of calamities; and, like the other Vedas, numerous hymns to the gods, with prayers to be used at solemn rites and religious ceremonies, excepting, as above-mentioned, such as are named Yajnya.

Mr. Colebrooke gives a passage from that part of the second, distinguished by the title of the White Yajurveda, the other being called the Black, confirming his opinions as above indicated, and important, as containing an enumeration of the Vedas, and of the various sorts of passages which they comprise: "As smoke and various substancces separately issue from fire lighted with moist wood, so from this Great Being were respired the Rigveda, the Yajurveda, the Samaveda, and the Atharva and Angiras; the Itahafa and Purana; the sciences and Upanishads; the verfes and aphorisms; the expositions and illustrations: all these were breathed forth by Him."

The commentators remark, that four sorts of prayers (Mantra), and eight kinds of precepts (Brahmana), are here flated. The fourth description of prayers comprehends such as were revealed to, or discovered by Atharvan and Angiras, meaning the Atharvava Veda. The Itahafa designate such passages, in the second part of the Vedas, as narrate a story. The Purana intends those which relate to the creation, and similar topics. "Sciences" are meant of religious worship; "verses" are memorial lines; "aphorisms" are short sentences in a concise file; "expositions" interpret such sentences; and "illustrations" elucidate the meaning of the prayers.

The Puranas here meant are not the mythological poems bearing the same title; but, as already mentioned, certain passages interpolated throughout that part of the Vedas called Brahmana, or divine precepts. This distinction is important. Under our article PURANA a pretty full account of theo metric romances will be found.

The subjects and uses of the prayers contained in the Vedas, differ more than the deities which are invoked, or the titles by which they are addressed; every line is replete with allusions to mythology, and to the Indian notions of the divine nature and of celestial spirits. For the numerous ceremonies to be performed by a householder, and still more for those endless rites enjoined to hermits and ascetics, a choice of prayers is offered in every stage of the celebration. It may be here sufficient to observe, that Indra, or the firmament, fire, the sun, the moon, water, the spirits, the atmosphere, and the earth, are the objects most frequently addressed; and the various and repeated sacrifices with fire, and the drinking of the milky juice of the moon-plant, or acid acetabas (see SOMALATA), furnish abundant occasions for numerous prayers adapted to the many ilages of those religious rites.

In describing the Vedas so replete with mythological allusions, Mr. Colebrooke does not mean a mythology which avowedly exalts deified heroes, as in the Puranas; but one which personifies the elements and planets; and which peoples heaven, and the world below, with various orders of beings. He observed, however, in many places, the groundwork of legends which are familiar in mythological poems; such, for example, as the demon Vritra, slain by Indra, who is thence familiarized Vrithubh (which sec,) but he did not remark any thing, except some detached portions, the genuineness of which appeared doubtful, that correspond with the favourite legends of those feats which worship either the Linga or Sakti, or else Rama or Krihna. Such portions, he reasonably supposes to have been composed in more modern times, when compared with the other parts of the Vedas. This suspicion is chiefly grounded on the opinion, that the feats which now worship Rama and Krihna as incarnations of Vishnu, are comparatively new: he did not find in any other part of the Vedas the least trace of such a worship. The real doctrine of the whole Indian scripture is the Unity of the Deity, in whom the universe is comprehended; and the seeming polytheism which it exhibits, offer the elements, and stars, and planets as gods. The three principal manifestations of the Divinity, with other personified attributes and energies, and most of the other gods of Hindoo mythology, are indeed mentioned, or at least indicated, in the Vedas. But the worship of deified heroes is no part of that fyltem; nor are the incarnations of deities fuggeted in any other portion of the text which he had seen, though such are hinted at by the commentators.

On the point of unity in doctrine, incorrupt with great sublimity and purity, we may refer to some translations from the Vedas by Sir W. Jones, in the last volume of his Works.

After giving strong reason for believing the Vedas to be genuine compositions, in opposition to ferous allusions of their being forgeries, or grossly interpolated, Mr. Colebrooke avows his opinion, that the greater part of the books received by the learned among the Hindoo will assuredly be found genuine;
The idea of impurity arising from the chanting of the Samaveda, is not uniformly held. Mr. Colebrooke informs us, "that a peculiar degree of holiness seems to be attached, according to Indian notions, to the Samaveda, if reliance may be placed on the inference suggested by the etymology of its name, which is expounded as denoting something which defines, fun." And this inference, we may remark, is countenanced by the circumstance of Kritham, when enumerating, in the Bhagavat Gita, various orders of beings and things, to the chief of which he compares himself, declaring, that "among the Vedas, I am the Saman." It may be said, however, that this Veda more especially relating to music, over which Kritham, the Hindoo Apollo, presides, he may advert only to its harmonious pre-emience.

iv. 125. "Let the learned," Menu commands, "read the Veda on every lawful day, having first repeated in order the pure essence of the three Vedas, namely, the Pranava, the Vyahritis, and the Gayatri." Of these fee under O'M. xi. 262. "A priest who should retain in his memory the whole Rigveda, would be absolved from guilt, even if he had slain the inhabitants of the three worlds, and had eaten food from the foulest hands."

253. "By thrice repeating the Mantras and Brahmanas of the Rig, or those of the Vyahuth, or those of the Saman, with the Upanifhads, he shall perfectly be cleansed from every possible sin."

264. "As a cloud of earth, cast into a great lake, sinks into it, thus is every sinful act submerged in the triple Veda."

266. "The primary triliteral syllable, in which the three Vedas themselves are comprised, must be kept as secret as another triple Veda; he knows the Veda, who knows the mystic sense of that word." Of which fee under O'M.

In the above texts from Menu, we see the propriety of the Hindoos to bring every thing into a ternary arrangement. The three Vedas, and the triple Veda, are ever recurring. In a hymn by Sir W. Jones to the Sun, or rather to its ruler, Surya, he says,

"Nor o'en the Vedas three to man explain
Thy mystic orb triform, though Brahma tun'd the Brain."

See SURYA. See also TRIBURTI for many instances of this disposition for triune classification.

The philosophical writers and their disciples, who profess to adhere closely to the doctrines of the Veda, are called Vedanta; which fee.

On the age of the Vedas, we have to observe, that Sir W. Jones (Af. Ref. vol. i.) rejects their claim to the very high antiquity that some warm advocates were disposed to ascribe to them; he could never believe that they were actually written before the flood; but ventures to affort, that they are far older than any other Sanscrit composition. And in IV. 11, he says, that he "firmly believes, from internal and external evidences, that three of the Vedas are more than three thousand years old." And in vol. iii. that they appear to stand next in antiquity to the five books of Moses.

In the preface to the Institutes of Menu, the learned translator deems the three first Vedas to have been composed about three hundred years before the Institutes, and about six hundred before the Puranas, which he is fully persuaded were not the production of Vyafa. The Institutes he supposes to have received their present form about 880 years before Christ's birth. By one mode of reckoning, the highest age of the Yajurveda is carried to 1583 years before the birth of our Saviour, which would make it older than the Pentateuch; and the Institutes must then be alligned to about 1280 years before the same epoch: but Sir W. Jones deemed the former date of 880 years B.C.
B.C. for the Institutes the more probable. This would give the Yajurveda an age, in 1815, of about 2995 years. Mr. Colebrooke (Al. Ref. vol. vii.) infers, from several data there given, the probability that the Vedas were not arranged in their present form earlier than the 14th century before the Christian era; but cautiously marks the inference as vague and conjectural: about 3200 would hence be assumed as the maximum of elapsd years since the present arrangement of the Vedas. And deducing, by Sir William Jones's method, the comparative age of the Puranas, they will be 2500 or 2600 years old at most; and the Institutes 2800. See Purana and Menu.

As to the relative age of the different Vedas, some differences of opinion will have been seen to exist. We shall only remark farther, that Mr. Wilkins, in the preface to the Gita, observes, that Krihna throughout the whole makes mention of three Vedas only; and those, the three first in their present order; the fourth, proving itself a posterior work, mentions him. On this being noticed to some Pandits who affixed to the translation, they expressed great astonishment at it, as it had escaped all the numerous commentators on the Gita. It may be remarked, in passing, that Menu is often mentioned in the Veda, and the Veda by Menu; a proof of interpolation somewhere.

It is evident that the Vedas are anterior to the hereof or reformation of Buddha; one of his leading innovations being the condemnation of the practice of killing and eating animals, as enjoined in the Veda, and by Menu. See Sects of Hindoes, and Sraeda.

So holy are the Vedas esteemed by the Brahmanes, that no individual of the fourth, or servile tribe of Sudra, is permitted to read them. In this interdiction are included several other divine works. Both the poems entitled “Mahabarat” and “Ramayana,” are likewise esteemed to contain passages and descriptions too awful for the eye of a Sudra: he may bear them read by a Brahman, who is likely to be careful as to what he communicates. Of this see under Mahabarat, Ramayana, Sects of Hindoes, Sura, and Vaidya.

The Yajurveda is declared by Menu, in a text quoted above, “to relate to mankind.” It is, as already noticed, ascribed to a celestial physician: it contains an entire Upanishad on the internal parts of the human body; with an enumeration of nerves, veins, and arteries, a description of the heart, spleen, and liver, and various disquisitions on the formation and growth of the fetus. From this, and from many texts of Menu, we may perceive that the ancient Hindoes were fond of reasoning, in their way, on the mysteries of animal generation; and on the comparative influence of the sexes in the production of perfect offspring. The physiological disputes on this latter point exacerbated, by mystical warmth, appear to have led to violent schisms in religion, and even to bloody wars. See Saraswati and Yoni.

There can be little doubt but the learned world would thankfully receive a faithful uninterpolated translation of such portions of the Vedas as tend to throw light on the state of knowledge among a people who so early engaged in such disquisitions as are contained in the Yajurveda, above indicated. These would, doubtles, be valuable, and are, indeed, necessary to complete the history of universal philosophy, and to supply the scholars of Europe with authentic materials for an account of the opinions anciently formed on this head by the philosophers of Asia. We will not say how far the Atharvane Veda may defer the honour of translation. It contains a most complete system of incantations and magical devices; and would be so far curious, as to evince that, both in antiquity and ingenuity, the demagogues of Europe are vastly outtripped by their fapiest brethren of the East.

We are not able to state the exact size or extent of the Hindoe scripture, or Veda. The following is as near an estimate as can be made.

The first, or Rig-Veda, contains about 10,000 verses, or rather flanzas, of various meausures. The second, or Yajur-Veda, is divided into two; the white and the black: together, they include about 9000 verses. The third, or Sama-Veda, about 3000. The fourth, or Atharva-Veda, about 6000. Of gloffes, or commentaries, it is not easy to form any but a vague estimate: but we are, we think, warranted in the opinion, that, supposing the whole could be collected and printed in the manner of our dictionary, they would form a work larger than this!

In all Hindoe writings connected in the leaf with theology, and, indeed, in many others, extracts from, and allusions to, the Veda, frequently occur. Several articles in this work contain such, and are farther explanatory of the contents of these revered volumes. Thofe, therefore, deprived of more information hereon, are referred to the following: Idolatry, Krishna, Matsyavatara, Saraswati, (in which is an extract of some length descriptive of the powers or energies of that goddef,) Shastah, Suttee, Sects of Hindoes, Sitaanta, Sraeda, Sura, Surya, Trimurti, Upanishad.

Veda is the correct way of writing the title of the Hindoe scripture collectively. In different parts of India it is variously pronounced; and it is variously spelt by European writers. Vadem and Bedam are occasionally seen: these are the modes of pronunciation in the Carnatic. Among the Mahattas, Bede, or Bhade, is not uncommon; and its reputed compiler is called Beafa, and Beafs Muni. (See Muni.) The Bengal alphabet having no v, Bed or Beda is the usual pronunciation in that quarter.

VEDAM, a name sometimes given to the Veda; which fece.

VEDANGA, in Hindoe Mythology, a name of the fun, more commonly called Surya; which fece. The name of Vedanga seldom occurs, as the fun; but it is applied to certain portions of books of divine knowledge, as they call them, derived from the Vedas. Of this see under our article Veda.

VEDANTA, in Philosophy, a fact among the Hindoes, so named from their theory being professedly founded on the doctrines contained in the Veda, or scripture, in a degree exceeding that of any other of the philosophical schools or eylms. (See Ved.) The fundamental tenet of this school consists, not in denying the exifence of matter, but in correcting the popular notion of it; and in contending that it has no exifence independent of mental perception; that existence and perceptibility are convertible terms; that external appearances and favations are illufory, and would vanish into nothing, if the divine energy, which alone sustains them, were suspended but for a moment. This opinion seems to have been adopted by Epicarchus and Plato, and was maintained in the last century by a writer of our own nation. The founder of this school is named Vyasa (which fece), and his theory is comprifed in a little treatife in four chapters. An attempt has been made to elucidate the obscurity of this writer by the judicious and learned Sankara, in his commentary on the Vedanta. (See some account of him under the article Sankara-Charita.) His chief work is entitled "Bafnea," Sir W. Jones, after reading this commentary with great at-
VEDANTA.

From a statement of the fundamental doctrine maintained by the disciples of the Vedanta school, it has been inferred that their philosophy is founded on the contemplation of one infinite Being, existing under two states or modifications. The first is that of a pure, simple, abstract Essence, immoveable and quiescent; the second is that of a Being displaying motion or active qualities. Under the first modification he is called Bruma, or the Great Being, and Kutatha, or He who fitteth on high; under the second, he is named Eet, the Lord, or Jee, the Soul: or we may say, that Bruma is Being in its state of simple essence; Eet is Being exerting energy, and causing the phenomena of the material universe; Kutatha is Being existing in sensitive creatures in its pure simple state: and Jee is Being in a sentient active state.

It is rare to find in Vedanta works any attempt to establish its doctrines by any process of reasoning. The authors announce the principles of their faith in a dogmatical authoritative style, as indubitable truths; or establish their affirmations by the authority of the sacred texts alone, and attribute disbelief to passion and ignorance. Sometimes, indeed, we do perceive an appearance of reasoning and argument, in support of the denial of a material world.

It will be perceived by those who investigate the Vedanta philosophy, that it does not correspond closely either with the Berkeleian, or with any other system, known in the western world. (See BERKELEY.) It does not teach that the Supreme Being is the soul of the universe, as was taught by Virgil (see MAYA); that animate beings are separate detached portions of his essence, or that the visible extended material frame of things is God; but it affirms that the world is one living, unextended, indivisible Being, who puts forth his energy, and excites in himself the phenomena of sensible things, as well as of sensation, passion, &c. In explaining this system, however, the writers frequently make use of such figures as may mislead one who reads only detached passages of Vedanta works, without examining closely the nature of their doctrines. Hence the Vedantas have been supposed to teach the doctrine of emanations; and it must be admitted that passages occur, even in the Vedas, apparently countenancing this supposition. (See MAYA.)

In the fourth or Atharva Veda it is said, 'as the sparks proceed from fire, so various kinds of animate and inanimate beings proceed from the incorruptible Being.' But the best commentators say, that these expressions do not mean that these are separate individual beings, but only whatever is beheld or perceived is the Divine Essence. The Vedanta opinions cannot be represented by any figure: they must be deduced from plain and simple declarations.

The Vedanta philosophy will be found to correspond with the Berkeleian in this important particular: both deny a material world, referring sensible things to the energy of a living Being. But the analogy appears to extend no farther. In another important particular they are strongly opposed: in maintaining and denying the existence of separate beings, upon whom this energy operates, existing in their minds the ideas of external things. (See MIND.)

There is no subject under our articles MYSTICAL POETRY, and SEEN.

Having offered this sketch of the Vedanta theory, the practical maxims of this very extended sect will be readily understood. They teach that perfection consists in redress that motion or action is the origin of the moral directions of good and evil, both of which must be renounced, as they involve and imply each other. To the attainment of this sublime state, it is required that the active faculties be sublimated, and the passions and affections subdued; that the individual be totally indifferent to external things, animate and inanimate, to parents, wives, children, relations, goods,

VEDA, Cape, in Geography, a cape of Spain, on the coast of Galicia. N. lat. 42° 19'. W. long. 8° 51'.
VEDRO, or VEEDRA, in Commerce, a liquid measure in Russia. The calk, farokowoi, or pipe of wine, contains 40 vedros; the vedro, 8 ofmucli or krulhka; and the krulhka, 11 ticharkays or cups. The vedro in Peterburg contains 621 French, or 752 English cubic inches; hence 1 vedro = 3⁄4 English wine gallons, and 3 krulhkas = 1 English ale gallon. Kelly’s Un. Camb.
VEER, in Geography. See Veercha.
VEER, in Sea Language, is variously used. *Veering out* the rope, denotes the letting it go by hand, or letting it run out of itself; thus, they say, *Veer more cable*; that is, let more run out.

VEDA, a river of Britain, the mouth of which is placed by Ptolemy on the south-east side, bounded by the German ocean. Horley differs in opinion concerning this river from Camden and Baxter; he supposes it to be the river Tyne, and they conjecture it to be the Were.

or to whatever causes pleasure, pain, &c. This furnishes a reason why, in some Vedanta works, language very dif-
dependent to the general rule and usage of the Hindoos. When the practice of rigid austerity, retirement from the world, and contemplation, this quiescent state is attained, the soul perceives that it is Being, and that Being is all things; and thus the soul becomes the one Infinite Essence. Some branches of this rigid austerity and contemplation are called *Tapas* and *Yoga*. (See under those words for some account of these practices; and under *Sects of Hindoos*, and Yoga, of those who practise them.) *Action*, say the Vedantis, or religious performances, do not conduct the soul to the state of the Eternal but to *Swarga* (which fee), where it continues, until the holiness it hath accumulated be nearly expended by the enjoyment of happiness; when it returns to earth, and takes a body corresponding to its remnant of virtue. Agreeably to this notion, action is condemned, as it tends to retain the soul in the prison of passion and affection. Still, while a person continues to perform the common acts of life, it is incumbent on him to attend to religious duties and rites.

It has been found expedient farther to modify the doctrine, in such a manner as to reconcile it with the ordinary avocations of life, on which depend the existence of society. Accordingly it is held, that the renunciation of the world does not require that a per son cease or depart from those avocations; but only that he preserve his mind in a state of perfect indifference and tranquility. "If it be alleged that the Puranas declare, that Bharata and others did not perform the acts of life; we would ask," says the Panchdhati, "why do you not listen to the Vedas, which declare that wise men eat, act, and procreate?"

It will be necessary to keep in mind that the Vedanta is a philosophical, not a religious system; and that a profession of its tenets is compatible with all the religious sects who admit the authority of the Veda. This may be said likewise of the Sankya, Nyayai, and other philosophical systems. The religious distinctions of the Hindoos result from the peculiar or exclusive veneration paid to a particular deity; and the adoption, as a spiritual guide, of those books which celebrate that deity as the great Being. On this point the reader may consult our articles *Krishna*, *Krishna*, *Saraswati*, *Saraswati*, *Sects of Hindoos*, *Sarawati*, *Sects of Hindoos, Sankya*, Siva, and others therein referred to, connected herewith.

When
When it becomes necessary to veer the ship, the sails to- 
wards the stern are either furled or brailed up, and made to 
shiver in the wind; whilst those near the head are spread 
abroad, so as to collect the whole current of air which their 
surfaces can contain. Hence, while the whole force of the 
wind is exerted in the fore-part of the ship to turn her 
about, its effect is considerably diminished, or altogether 
destroyed, on the surfaces of the after-fails. The fore-part, 
accordingly, yields to the above impulsion, and is put in 
motion; and this movement, conjuring with that of the 
wind, puffes the ship about as much as is necessary to pro- 
duce the effect required. When she is turned so that the 
wind will act upon that quarter, which was formerly to 
leeward, her circular motion will be accelerated by extend- 
ing some of the sails near the stern, as the mizen, and by 
placing those at the prow more obliquely, which will wheel 
the vessel round with her bow to the windward; in the 
same situation, with regard to the wind, as when close- 
hauled, or tacking. When the tempest is so violent as to 
prevent the use of sails, the effort of the wind operates 
almost equally on the opposite ends of the ship, so that the 
main and mizen masts are furled at the head and stern—counter 
balance each other. The effect of the helm is also consider- 
bly diminished, because the head-way, which gives vigour 
to its operations, is at this time feeble and ineffectual. 
Hence it is necessary to destroy this equilibrium which sub- 
stitutes between the masts and yards aore and abaft, and to 
throw the balance forward, in order for veering. This is 
accordingly performed by bracing the foremost yards across 
the direction of the wind, and arranging those on the main- 
mast and mizen-mast directly in the line of the wind. If 
this expedient proves unsuccessful, and it is absolutely ne- 
cessary to veer, in order to save the ship from destruction, 
by overfetting or running ashore, the mizen-mast must be 
instantly cut away, and even the main-mast, if the yet re- 
 mains incapable of answering the helm by bearing away 
between the wind. Falconer.
V E R I N G, in H e f f a n d r y, a term borrowed of the sailors, 
and used for the turning of two furrows towards each other, 
as they must do to begin a ridge; they therefore call 
the top of a ridge a veering; and they call the two furrows 
that are turned from each other at the bottom between two 
ridges, a hening; that is, an ending, because it makes an end 
of plowing ridges.

county of Verden; 10 miles E.N.E. of Rotenburg.
V E G A, L o p e z de L a, or L o p e - F e l i x de V e g a- 
Carpio, in Biography, a celebrated and voluminous Spanish 
poet, was born of a noble family at Madrid, in the year 
1562. Having been educated in the university of Alcala, 
he occupered several honourable posts, and served on board 
the grand armada defined against England. After the 
death of his second wife, he took holy orders at Toledo, 
and obtained admittance into the congregation of priests at 
Madrid; acting as precentor, and being himself one of the 
third order of Franciscans. By favour of pope 
Urban VIII. he was honoured with the insignia of the 
knight's of Malta, and with the title of doctor of theology. 
He died in 1655, at the age of 73. He was eminently dis- 
tinguished as a poet, and regarded as the father of the 
Spanish drama, excelling, as some have asserted, all poets, 
auxient and modern, in this kind of composition. His 
"Theatre" occupies twenty-five volumes, each of which 
takes twenty plays of various descriptions. One of his 
biographers fays of him, that "the innudation of Vega's 
fancy leems to have been no more than a deluge of very 
orinary matter, in which there is little to be praied but 
an easy eloquence of language, and a faculty of dramatizing, 
after a manner, stories of every kind. Three hundred 
pieces could not possibly have been composed otherwise. 
Nor was this the principal portion of his literary labour; 
for he has himself affirmed, that upon a calculation it would 
appear, that he wrote five leaves of MS. for every day of 
his life." The high degree of admiration he inspired in 
his own country appeared from the numerous eulogies of 
which he was the subject after his death. Moren. Gen.

itory, on the route from Thynz to Thylette, between 
V E G E T A B L E S, in Agriculture and Gardening, are all 
such plants as are found capable of affording useful products 
as food for man, and different sorts of live-flock. They 
are constituted and composed of soft and fleshly and solid parts, 
the latter of which are formed and arranged in such a 
manner as to afford proper firmness and support in their 
different growths; and from which proceed those which 
are often considered as, in some measure, distinct and different 
in their nature and uses, as the roots, the stems, the leaves, 
the flowers, the fruits, the seeds, and some others.
The first of these, which differ greatly in different sorts of 
gecetables, are the parts which connect them with the 
earth or foil, and the main source of their nourishment and 
support. They are, in all cases, more or less fibrous in 
some of their parts; and the more perfectly this takes 
place, the more capable are they of drawing nourishment 
from the ground on which they grow. It is, consequently, 
the fibrous radicles and the leaves that constitute the media 
through which the growth and increase of vegetables are 
effectecl. The fixing of these parts in the earth, too, by 
the ramifications which they send forth, prevents the vege-
tables from being overturned by winds and other causes. 
The form or shape and uses of these parts in different kinds 
of vegetables differ very materially; having in some cases 
a branching lateral growth, in others a knobby, and some- 
times that which is directly downward, in some infaces 
is fleshly and edible, and in others woody or ficky, and of no 
value.
They are very similar in the nature of the different divi- 
sions of their parts to the stem or trunk and branches; and 
may, indeed, be said to be a sort of continuation of the 
former, terminating in minute ramifications and filaments, 
and in leaves; and by burying the branches of certain 
trees, as the willow, in the earth or foil, as practised by 
Woodward, and since repeated by many others, and elev- 
ating the roots in the atmosphere, there is, as it were, an 
involution of the functions of them, the roots producing and 
becoming buds and leaves, and the branches shooting 
forth into radical fibres and tubes, and forming roots. See 
Root.
The second of these parts are those which stand next in importance in vegetables, when considered merely as fuel, and which include the branches as well as all the solid parts of them, conmilting principally of different coasts, as bark, flesh or wood, according to the nature of the vegetable, and pitch, or the middle part. These coats or coverings are differently formed, modified, and constituted, so as to be of different uses in their economy. The part, or layer, which is placed next to the wood, is composed, in vegetables of the tree kind, of a soft white subflance, not easily discernible in some fruits of trees, but harder and more apparent in others. It is, as it were, an imperfect wood, or in the state between bark and wood. The wood is the compact, fibrous, hard part or subflance which is disposed in the middle of trees, which in annual and biennial vegetables is called the flesh, as has been seen already. Between the above coat and the wood, a new ring of a softer nature is formed every year, which gradually loses its softness as the cold season advances, and which towards the middle of winter is converted into a solid ring of wood. These annual rings, which are visible in most trees, are produced through transversely, serve as marks by which to determine their ages in some cases. They seem to decrease in breadth as the trees advance in age; and as they are found to be very unequal throughout in their dimensions, their breadth probably varies as the season may be favourable or otherwise. The wood, however, does not only differ from the coats or bark in the degree of hardness, but likewise in its structure, which is essentially different; and the seeming conversion of bark into wood, is imagined by some to be entirely a deception.

Thus, if the branch, item, or the root of a tree be cut in a transverse manner, it usually displays three distinct bodies or parts; the bark, the wood, and the pitch; each of which is again susceptible of a new division. The bark, where perfectly formed, has a thin covering, that may easily be separated; it is in laminae or scales, which, in old trees, are moily in a loose and decaying state. It is not vascular, but merely defends the interior parts from injuries. It is supposed to be a part of little importance in forest-trees, and the larger shrubs, the bodies of which are very firm, and of strong texture; but in the reeds, the rush, sedge, and the plants which have hollow stalks, it is of great use, as it is of very great strength, and appears constituted of a sort of glabby net-work, which is chiefly siliaceous earth, as has been lately ascertained. This is the case in wheat, in the oat, and in different other plants; in some of which it exists in large quantities, and is general in this part of those of the hollow kind. It is serviceable as a support as well as protection from insects in such cases.

The most interior part of the bark is composed of layers, the numbers of which vary with the age of the tree; so that on cutting this part of a tree of several years standing, the productions of different periods may be distinctly seen, though the layer of every particular year can rarely be exactly defined or ascertained. The functions of the different parts of the bark are of great importance to vegetables.

In regard to the wood in trees, it is composed of an external or living part, called fap-wood, and of an internal or dead part, termed heart-wood; the former of which is white, and full of moisture, and in young trees and annual plants, reaches even to the pith. It is the great vascular system of the vegetable through which the sap-juice rives, the vessels in it extending from the leaves to the most minute filaments in the roots. Its structure has different important uses in producing new arrangements and forming new wood.

In respect to the arrangement of the fibres of the wood, there are two distinct appearances in them: as the fibres of white flowering onions, which is in the Smyrna, to the circumference, and which constitute what is termed the fibre grain of the wood; and the numerous series of concentric layers, which are commonly denominated the spongy grain, the number of which denotes the age of the tree, as already suggested. The former has many important functions, and is the most distinct in forest-trees; though annual shrubs have even a fyltem of fibres similar to it. See Tim-ber, Sap, and Alburnum.

The item parts of some vegetables are quite hollow; partly, it is supposed, from such vegetables requiring a more than ordinary supply of air in their support, as they are generally those which are of a quick growth.

The pitch is the soft, white, innermost subflance of vegetables of the tree and other kinds, that is situated in the centres of the items.

In the very infancy of the vegetable it occupies but a small space, but gradually dilates; and in shoots of the annual kind, and in young trees, offers a considerable diameter. Being acted on by the heart-wood, as predisposed by the new layers of the fap-wood, in the more advanced age of the tree, it begins to diminish, and in very old forest-trees wholly disappears. As it has lately been wholly removed in different young trees, which continued to live and increase; it is evidently only an organ of secondary importance. In early shoots, in vigorous growth, it is filled with moisture, and is a reefer of fluid nourishment, perhaps, at the time when it is most wanted. As the heart-wood forms, it is more and more separated from the living part, the fap-wood; its functions become extinct, it diminishes, dies, and ultimately disappears. See Stalk and Trunk.

The third, or the leaves, are parts which are essential to the existence of vegetables; as when, either of the plant or tree kind, wholly divested, or only stinted of a considerable part of them, they do not shoot in a vigorous manner. They are produced from the coats of the stalks or stems, and are of the soft fleshy thick kind, or the more thin, barkty, or woody fort. They are capable of affording nourishment, and are maintained by the nutrient fluid matters which they hold in reserve in their soft subflances, and by the dew, air, and moisture, which they take in and throw off.

In all cases the leaves are similar in their interior organization, and perform the same functions as the above parts, only their structure is finer and more minute. The fap-wood spreads and extends itself from the footstalks into the very extremities of the leaves; it preserves a vascular fyltem, and its living powers; some parts of the former of which may be distinctly seen in the leaf. A material use of the leaves is, the exposure of the sap to the influence of the air, heat, and light; for which their surface is extensive, the tubes and cells very delicate, and their texture porous and transparent. In the leaves, much of the water of the sap is evaporated; it is combined with new principles, and fitted for its organizing functions, and probably passes, in its prepared state, from the extreme tubes of the fap-wood into the ramifications of the cortical tubes, and then descends through the bark. On the upper surface of leaves, which is exposed to the sun, the external covering is thick but transparent, and is said to be composed of matter polished of little organization, which is either principally earthy, or consists of some subflance of the homogeneous chemical kind. That in the grases it is partly siliaceous, in the leafy ruminous, and in the thorn and maple principally constituted by a subflance analogous to wax.
By these arrangements, any evaporation, except from the appropriate tubes, is, it is thought, prevented. On the lower surface of them, the external coat is a thin transparent membrane full of cavities; and it is probably altogether by this surface, it is said, that moisture and the principles of the atmosphere necessary to vegetation are absorbed or taken up. The leaves in the greater number of plants annually decay, and are reproduced; their decay takes place either at the close of the summer, as in very hot climates, when they are no longer supplied with sap, or on account of the dryness of the soil, and the evaporating powers of heat; or in the autumn, as in the northern climates at the commencement of the frosts. In common cases, the leaves prefer their functions no longer than there is a circulation of fluids through them. The colour assumed in the decay of the leaf, seem, it is said, to depend upon the nature of the chemical change; and that as acids are generally developed, it is usually either reddish-brown or yellow; yet there are great varieties. Thus, in the oak it is a bright-brown; in the beech, orange; in the elm, yellow; in the vine, red; in the fycamore, dark-brown; in the cornel-tree, purple; and in the woodbine, blue. The cause of the preservation of the leaves of evergreens during the winter is not well known. It is found that the force of the leaves is much less in vegetables of this sort, and there is probably a certain degree of circulation throughout the winter season; their juices are less watery than those of other plants, and probably less liable to be congealed by cold, and they are defended by stronger coatings from the action of the elements. The production of the other parts of the plant may be noticed to take place at the time the leaves are most vigorously performing their functions. If the leaves of a tree be stripped off from it in the spring, it uniformly dies; and when many of those of forest-trees are injured by blasts, the trees are daylight always to become flag-headed and unhealthy in their growth.

The leaves, it is said, are necessary for the existence of the individual tree; the flowers, noticed below, for the continuance of the species. In the flowers there are several different organs or parts, the forms, vavceral nature, texture, and organization of which serve different important uses and functions. That which contains the rudiments of the seed has it never formed as reproductive, without the aid of the influence of the pollen, or fecundating dust provided for the purpose. This proper impregnation is, of course, necessary to the continued succession of the different vegetable tribes. It has been noticed, that all the parts of a vegetable seem to contribute to the formation of the flowers and fruits of plants; as, although the latter do not swell and ripen until after the former have fallen, their rudiments or first beginnings are in the flowers, of which they properly make a part. These last are consequently temporary parts of vegetables, allotted to the purposes of generation, terminating, as it were, the old vegetables, and beginning the new ones. Fruits consist of nearly the same parts as the items of vegetables, as a fort of soil or fine coat, which is a production or continuation of that of the bark of an outer soft pulpy fibulation, and is the same as that continued from the bark, only that its vehicles or cells are larger, and it is more succulent and juicy. There is commonly an inner pulp, which is next to the stone and the core itself is nothing more than a hard woody covering, that includes the feed. It is to be noticed, however, that the formation of the fruit is very various: in some cases, the seeds are dispersed through the pulpy fibulation; in some, instead of a core, a strong woody material is met with, inclosing the seed or kernel, which, from its great hardhefs, is termed a stone; in some, there is a number of seeds; and in others, only a single seed, included in a large mass of pulpy matter. See Fruit.

The seeds are the deciduous parts of vegetables, each seed including the rudiment of a new plant, imbued with the vital principle, which it is capable of retaining for a vast length of time. A seed consists of different parts, as that which is necessary to the production of the new plant or vegetable within the seed, termed the corcule; which is divided and disfigured into the fealy ascending part, named the plume, and the plain descending part, called the rofel; with different others of less importance, some of which are perishable. It has been commonly supposéd, and not without probability, that the perfect plant, or the organization necessary to it, exists in the seed, surrounded by a quantity of farinaceous matter, which serves to absorb moisture, and to furnish nourishment to the corcule, until its parts are sufficiently unfolded to draw support from the soil in which it is placed. This is finely illustrated in the dwarf kidney bean, which, when steeped some time in water, and it begins to swell, may be easily separated into its two lobes, between which is seen the nascent plant or vegetable. The stem, and its connection with the lobes, too, are clearly seen, and numberless vealls ramify through the lobes, which directly communicate with the embryo plant or vegetable. And on the external surface of the seed are absorbent vealls, that take up moisure, by which a sort of fermentation is produced, and a liquid material formed, elaborated and prepared by a particular process, which is proper for the nourishment and support of the plant or vegetable, in its first tender growth. In this early growth, the lobes of the seed, which are provided with a mealy material, are likewise found necessary. And the first leaves, or those which are called feminal, are thought to appear not less necessary than the lobes to the perfection of the plant or vegetable; as, if they happen to be broken off or destroyed, the plant or vegetable experiences a proportional loss of strength and vigour in its growth.

There is, therefore, to be distinguished in every feed an organ of nourishment, a nascent plant, and a nascent root. The first of these, in wheat and many grasses, is a single part; in other instances, it consists of more than two parts; but in the greater number, it is simply divided into two parts.

The feed, which is the last production of vigorous vegetation, is wonderfully diversified in form. That being of the highest importance to the organs of nature, it is described above all other parts of the plant, it is said, by felt pulpy fibulations, in the esculent fruits; by thick membranes, in the leguminous vegetables; and by hard shells, or thick external coverings, in the palms and grasses. Though the matter of the seed, in its common state, may appear wholly inert and inactive; when acted upon by moisture, heat, and air, it soon distinctly develops itself, and becomes a complete plant in root and stem.

The above observations have been chiefly taken from the works of Hooper and Davy, to which the reader may be referred. See Seed.

As vegetables are supplied with proper vealls, those of the absorbent kind on the surfaces of them take up the nutritious fluid or material, and convey it to the different parts. The surface of a plant has two sets of absorbents, as already seen, which constitute the absorbent organ of vegetables; as the mouths of the vealls of the radicles of the roots, and those on the surfaces of the leaves. The root, as long as it remains soft and tender, imbibles and takes up the nutritious juices from the earth, by means of the absorbent mouths of its vealls; but as soon as it be-
comes ligneous, it emits radicles on every side, which continue the absorption, and convey the matters first to the root, and then to the whole plant or vegetable. Thus, if a plant or tree be transplanted, it succeeds with greater certainty, the more absorvent radicles are preferred with the root. The leaves absorb matters from the surrounding atmosphere, in the same manner as the radicles do from the earth, and convey them to the other parts of the plant or vegetable. It is suppos'd that, by means of the absorbents, water is distributed to every part of the plant or vegetable, and constricts its principal aliment; as, deprived of this universal fluid, it droops and dies; but, by its influence, is not only nourished, and the vacuolar parts of the whole fabric dilated, but it contributes greatly to excite the languishing fibres, and in this way to increafe the vital power of the vessels. By means of this sytem of vessels, too, the atmofoherial air, which is effential to the growth of vegetables, is absorb'd or taken up; as plants in vacuo cannot be evolved from the feed, nor can they afterwards vegetate. This is most probably the reafon why feeds, buried very deep in the earth, do not vegetate, but die. See Sap and Vegetation.

There are many matters or principles in different kinds of vegetables, which render them particularly useful in the way of food, or beneficial in the products which they afford. The starchy and saccharine principles are particularly important, as poiffing the qualities of fattening animals in a high degree. See Starch, Saccharine Matter, and Vegetable Matter.

The bitter principle prevails very extensively in vegetables, and the natural fort of it is of great importance and utility in the art of brewing, as checking fermentation, and preferring fermented liquors, &c. And there are many other principles in them, which contribute to different useful purposes in several ways. See Oil, Volatile Oil, Wax, &c.

The particular nature and properties of the few different principles of parts of vegetables may be seen explained in Davy's Elements of Agricultural Chemistry.

The quantities or proportions of nutritive or soluble matters, which are contained in different vegetables, or substances of that kind, are very different, as fhewn in the table given below from the above work, which comprehends the quantities of this fort of matters which are afforded by a thousand parts of different vegetable substances, when submitted to experiment, green, and in their natural states.

These...
VEGETABLES.

No differences have been found in the nutritive produce of the crops of different grasses cut at the same season, which could render it possible to establish a scale of their nutritive powers, but probably the soluble matters of the after-math crop are always from one-sixth to one-third less nutritive than those from the flower or seed crop. In this crop, the extraneous and saline matters are certainly usually in excess; but the after-math hay, mixed with summer hay, particularly that in which the fox-tail and soft grasses are abundant, would, it is thought, produce an excellent food or fodder.

In the clovers, the soluble matter from the Dutch clover is said to contain most mucilage, and most material analogous to albumen: all the clovers contain more bitter extract and saline matter than the common proper grasses. When pure clover is to be mixed as fodder, it should, it is said, be with summer hay, rather than after-math hay.

Other observations on this interesting subject may be seen in the appendix to the above work.

In cultivation, much use and advantage may, in many cases, be derived from changing the natural habits of vegetables, by fowing the seeds of them or planting them at unfavourable seasons, by placing them in more dry and warm, or more cold and moister situations, and by altering the time of their flowering, or the length of their duration, by cutting parts of them, or in other ways; as by such means some of them, though annual in their nature, may be made to last and afford crops for two or for several years. Others may furnish two or three green crops the same season, and an early one in the succeeding; and so on in a variety of instances in the garden as well as in the field.

VEGETABLES. Injuries or Disturbance of Parts of the affection and mischief which are produced in them by different agencies, as those of frost, lightning, insects, and some others. It is well known, that trees of the apple and some other kinds, in field fruit-grounds, orchards, and gardens, have their buds, blossoms, and other parts, often affected or destroyed by a fort of blight or canker induced by such causes; in consequence of which there are great failures in the crops of them. The mischievous effects of frost in this way may frequently be clearly traced, though they are seldom greatly injurious, when it is of the dry kind, unless it be very severe; but most certainly so, when it succeeds to large falls of rain. Sudden transitions from heat to cold are hurtful to vegetables: by warmth the vessels of them are expanded, and their juices flow freely: a sudden application of cold causes a sudden contraction of their parts, without a proportionate diminution of the fluids which they contain, which being thus unnaturally checked in their current, become stagnant and diseased. Rain is congenial to the growth of vegetables; and while Nature dispenses them to open all their pores, by which its influence can be received, when overtaken by frost in such a situation, the consequence must be injurious or fatal. It has been said by a philosophical writer, in speaking of the action of cold or frost, that besides its opposition to the adequate fluidity of the vegetable juices, it must be unfriendly to the animation of the solids, causing either local canker, or death of the whole vegetable. That when the vegetable fluids are chilled, and converted into ice, their bulk is vastly enlarged, and this enlargement sometimes takes place with such extreme violence as to rend them in pieces. In this way, frost, it is thought, destroys those parts of vegetables which are most succulent, particularly in that form of it which is called hoar-frost, or rime, so common in the spring season. The moisture of fog too is said to be equally mischievous, as far as it extends. Thus, in a fruit district, in one night at this season, a molt promis-
ing blossom has been cut off; the elm, oak, and ash, being injured at the same time: the line of devastation was precisely marked, proceeding in a horizontal manner through a certain vale tract, to the height of about thirty-five feet; the trees that grew on higher ground not being touched. The explanation of this circumstance seems, it is said, to be, that the fog, which rife more or less every evening, especially after a warm day, was, during the night, in this infancy, suddenly succeeded by a smart frost, which leaved the moulded parts to the point of elevation of the fog, and protected the mistletoe. Cold winds coming after a day or two of fine weather, may likewise prove destructive of the blossom in such cases of apple-trees in these fruit-grounds. On this account, in a northern exposure, the fruit is not unfrequently preserved, while in others it is destroyed; for the sun, not having much influenced the trees in this situation, they are left to the prevailing temperature of the sea, and thus enabled to bear the cold north-easterly blasts of the night without being hurt.

Though the second of the above causes is much believed to be hurtful to the trees in fruit-grounds by those engaged in them, the opinion has been considered as unfounded by some. If, however, the partial manner in which some trees and hedges are affected be considered, it will be difficult, it is thought, to account for the effect in any other way. This cause, like that of frost, may affect vegetables by its expansive power, bursting their velvets as it passes through them. In some cases, a single limb of a tree, in one night, loses all its foliage, and ceases to vegetate: in others, one tree of many in a fruit-ground; or on a row of trees in the same direction; and sometimes, whole fruit-grounds are affected in the same manner, and are difficult of recovery. The mischief is mostly done in a night, and with great uncertainty, as neighbouring trees in the very same directions often escape. In respect to the leaf of these causes, it has been observed, that frothy nights, with a north-eaft wind, in the spring, succeeding a warm day, are particularly injurious to the blossom of the apple; the warmth of the day hatches the ova or eggs of the insect which breezes in it, while the coldness of the night, by checking the progres of the sap, keeps the blossoms in its half-expanded state, to form a nidus for them. The opinion of apple-growers, too, is in support of this in most districts and situations. But whether insects are caused in this way, or by the diseased state of the trees, the more promising mode of preventing the ravages and destruction which they commit on the leaves, buds, and blossoms of such trees, is that of smoking them well by means of some proper substance, to which a little sulphur has been added. In this way they may moly be got the better of without much trouble.

The other causes of mischief have been noticed under their proper heads.

Many other forts of vegetables of the tree and other kinds are likewise liable to be affected, injured, or destroyed in their parts by these causes, the prevention of which may be attempted by similar means. See Difficult of Plants in Smith's Introduction to Botany.

Vegetable Acid. See Acid, and Vinegar.

Vegetable Ashes, in Agriculture, the substances of this sort which are produced from vegetables of different kinds by incineration. They differ much in their nature and quantities as afforded by different vegetables. In general, those of the herb fort furnish four or five times, and those of the shrub kind two or three times as much ashes as those of trees. The leaves in common produce more than the branches, and the branches more than the trunks. Those burnt in a green flate afford more ashes than such as are consumed in a dry condition. The quantities of ashes that are afforded by some common vegetables are, in 10,000 parts of the thistle, 53 of ashes; in the fame number of fern, 62; in that of the low-thistle, 105; in wormwood, 730; in vetches, 275; in beans, 200; and in funitory, 790; while in the fame number of parts of the poplar-tree, 7 of ashes are only afforded; in the beech, 12; in the oak, 15; in the elm, 39; and in the vine, 55. Such vegetable ashes as contain alkaline, matter, where they can be applied to land with advantage in some cases. The oxides of metals are sometimes found in the ashes of vegetables, but only in very minute quantities. In some ashes the vegetable ashes are of a reddish-brown appearance, they are mostly impregnated with the oxides of iron; but where they have a black or purple cast, with that of the oxide of manganese; and where these different colours are blended, they contain both such substances of the oxide kind.

The different saline compounds contained in vegetables, or afforded by the incineration of them, are extremely various, and have been considered under their several proper heads. See Sulphate of Potash, &c. Phosphate of Lime, &c.

The quantities of soluble saline matters, metallic oxides, and other substances which are afforded by the ashes of different vegetables, may be seen in a table inserted in the "Elements of Agricultural Chemistry."

These points may serve to direct and assist the farmer in the preparation and application of vegetable ashes in the most economical and beneficial manner, where they can be had recourse to with propriety as a dressing on land, or over crops of some kinds. See Ashes and Wood-Ashes.

Vegetable Earth, or Mould, that fort of fine reduced earthy material, which is formed and produced by the destruction and decay of different vegetable productions and materials, either upon the surface, or in the more interior parts of the land. The term is, however, more generally applied to the peculiar earthy substance, or body, which constitutes the superficial layer of fine black or dark coloured mould, in which plants, for the most part, strike or take root, and grow in every fort of ground or soil, and which varies very greatly in different situations and circumstances, in consequence of the variations that happen in respect to its depth, and the progress it has made towards the flate of perfect decomposition and destruction, as well as from the nature of the vegetable substances and matters of which it is constituted and composed. It has been supposed, too, as acquiring some diversity or difference of quality on account of its being more intimately or more loosely mixed and incorporated with the other bodies and materials that are found to constitute land; and, likewise, that the earthly matter which is formed from the destruction of some particular forts of vegetable materials, may be better suited for the purposes of vegetation than that which proceeds from others. It is an earthly material, which, besides being produced both by the diffolution and reduction of vegetable matters, as above, may probably be partly too acquired from the air, water, and light; by the procefs of vegetation, and partly from the properties of the lands in or on which it exists. In some cases it is of very considerable depth, while in others it forms merely a thin superficial coat or covering of the land; and there are still other cases, in which it is scarcely visible, or met with at all.

It may be noticed, that vegetables, in consequence of their having in their composition a large proportion of mucilaginous matter in a flate of mixture with their other materials or substances, especially in some forts, are in some de-
V E G E T A B L E S.

Gree capable of being dissolved in water, though the external coats or coverings of living plants, principally on account of the resinous material that enters into their composition, are preferred from its action and effects. It is plain, that in consequence of the fluid of these circumstances, and that of earthly matters being contained in them, which had been taken up in the fluid of solution or diffusion with their fresh fluids or juices while growing, that considerable quantities of vegetable earth or mould must be continually formed and deposited on lands by the natural diffusion and decay of such bodies. But its formation and provision are much more abundantly effected by means of the putrefaction and destruction of such vegetable productions as are cut down, or otherwise destroyed, on the surface of the land, and the laying of different kinds of manures and compost materials upon it.

In cafes where these have been in great abundance for a long time, there is mostly, it is said, a deep rich surface bed of this earth or mould; but that where few vegetable products, and those of the less luxuriant kind, have been left to undergo the above processes, or little affilience given by means of manures, the crust of surface earth or mould is commonly very thin and poor. In all cafes, it is evident that the diffusion and decay of vegetable materials must be greatly promoted and expedited by a proper degree of moisture, and suitable state of heat; the atmosphere being at the same time in a proper condition for the purpose. The clofe and flagnated state of different forts of luxuriant tall growing crops of the grafs, herb, plant, or other kinds, have likewise much effect in the forming and elaborating of this mouldy material, by the decaying foliage thereby promoted, falling down and being so much deposited on the land.

All these materials, during the state of decay, undergo different changes in their constituent principles or parts; the water which they contain being decomposed, pure air or oxygen is absorbed, heat difengaged, and new compositions of the aerial and faline kinds formed; by which means a number of matters are prepared and fitted for the use and support of vegetable life, which could not have been supplied in any other way, as well as rendered much more extensively applicable in this intention than they could otherwise possibly have been.

It is advised, that in order to promote the formation and production of vegetable earth or mould, recouerse should be had not only to such substances as accelerate the putrefactive processes, but also to such as have a tendency to increase the falsnosity of the vegetable earth or mould of the land itself: and that the fluid of these purposes may be promoted and attained by the application of such substances and materials as have been found useful in changing vegetable matters into the state of mucilage, such as the carbonate of lime, or effective lime, marle, chalk, and calcareous matters in general, and likewise some earthly saline substances, as the refuse of salt manufacturies, and others of that kind. That the latter of such substances is to be attempted by the use of different substances and matters that are of an alkaline nature; such as the afhes produced by the burning of various green vegetable materials, the urine of animals, the liquor of dung-hills and pits, night-soil, and many other such animalized matters and substances. There are many other ways, too, in which vegetable earth or mould may be made and rendered more abundant in land; such as the frequent growth of those kinds of crops that cover the ground in a close full manner, so as to produce a confined flate of the air, as already suggested; the consuming upon, or turning down into the ground, full, rich, and succulent green crops, by which much vegetable matter is brought into a state of decay; and

by the caufing of the deftruction and evacuation of infect of various forts, which are predominant in land, by the use and application of such substances and matters as have the power of effecting these different purpoifes and intentions.

It must be noticed, however, that it has been remarked by the writer of the work on the "Connection of Agriculture with Chemistry," that too large a proportion of vegetable matter in land, particularly where it is exposed to be much acted upon by the oxygene principle of the atmosphere, is liable to render the ground too loose and open in its nature for the growth of most sorts of crops of the grain kind; winter corms being, especeially from the sudden alternations of frost and thaw, frequently thrown out of fuch lands, and almost wholly destroyed. In cafes of this nature, great advantage may, it is faid, be derived from the use of different matters of the faline kind, and lime in its faturated flate, as by fuch means the vegetable parts of the land will be brought to their proper productive flate, in so far as the growth of crops is concerned.

It has been conceived too by the fame writer, that the abstraction of the oxygene principle from the surrounding atmosphere, or what is termed the process of oxygencation, is the principal cause of the retention of vegetable matter on the surface of the earth, in several earths, as well as others, but especially in such as have been long in a state of tillage, or under the plough. This process having the power, it is supposed, of rendering the vegetable matter lefs destructible, scarcely any of it being carried away in a state of diffusion by rains, or water in other ways, an accumulation takes place, which, under other circumstances, could not have happened. The indestructible state of vegetable matters under these circumstances, and their conftant accretion, may, it is thought, be referred to the infoluble compounds produced by the action of pure air on such infamblable substances. The infolubility, to a certain degree, of this system adopted by nature, is undoubtedly, it is fuppofed, to be preferred to one more completely folaible; for it is evident, it is faid, that if putrefaction or oxygencation had poffeffed the power of rendering all the vegetable matter, by a speedy process, folaible in water, two pernicious conftquences must have followed: the rains would have washed down fuch extracts, and folaible matters, as faft as formed, into the rivers and springs, contaminating the waters, and rendering them unfit for the exifence of fifties, or for the ufe of terrestrial animals. The fcin of process of time would thereby receive all the vegetable and animal produce of the dry land, and the earth would ultimately become barren, confufling alone of the fimple earths, without any admixture of vegetable matter; confequently there could be no accumulation of this fubflance on the surface, as is the cafe to an immense degree at prefent. As fuch, there cannot, it is conceived, be a doubt, but that the prefent incomplete processes of putrefaction, oxygencation, or folution of organic bodies, has been efftablifhed by the great Creator of all things for wife and benevolent purpoifes; especeially when it fhall be underflood, that the apparent infperfections of this, to a certain degree, infoluble fystem, are, as they respect agriculture and vegetation, to be remedied, when neceffary, by the ingenuity and industriy of man. It is confequently fuppofed that the vegetable matters which exift in lands, from their admitting different degrees of this process, and, of course, becoming more or lefs infoluble, have different powers in forwarding the growth and support of plants. Where the exposure to these causes has been long, they are generally more infoluble in their nature than where the contrary has been the cafe. See Oxigenation.

Upon the whole, vegetable earth or mould should be accumu-
nulated in grases lands as much as possible; but where grain
crops are to be raised, a proper mixture of other earths
is necessary, to give them stility, and prevent their being
thrown out of the ground.

Vegetable Fly, in Natural History, an insect found in the
island of Dominica, and (excepting that it has no wings) re-
sembling the drone in size and colour. In the month of
May this insect buries itself in the earth, and begins to
vegetate. By the latter end of July the tree is arrived at
its full growth, and resembles a coral branch; being about
three inches high, and bearing several little pods, which
dropping off become worms, and afterwards flies, like the
English caterpillar. Dr. Hill, in his account of this pro-
duction, to whose examination it was submitted, observes,
that the Cicada is common in Martinique, and in its nympha
state, in which the old authors called it tetitogemata; it buries
itself under dead leaves to wait its change; but when the
seafon is unfavourable, many perish: and that the seeds of
the clamaria fabolifera, which is a fungus producing fosbales
or shoots from its fides, and growing in putrid animal bodies,
find a proper bed on this dead insect, and grow. This, he
says, is the fact: though the untainted inhabitants suppose a
fly to vegetate, although there exists a Spanish drawing
of the plant's growing into a trifoliate tree; and it has been
figured with the creature flying with this tree upon its

Vegetable Oil. See Oil.

VEGETATION, in Vegetable Physiology. See Ger-
mination, Circulation of Sap, Spiral Vessels, Leaf,
&c.

Vegetation, as it relates to Agriculture and Gardening,
is of considerable importance, by explaining the nature and
means by which plants and crops receive nourishment and
support, and are the beef promoted in their different growths.
In respect to grain, feeds, and fets, it seems evident, from the
experimental enquiries of Mr. Gough and others, that during the
act or procels of their germination or infant vegetation,
they draw the oxygen principle from the surrounding atmo-
sphere, part of which is retained, and the remainder thrown
off, charged with a portion of carbon; and that, in this proc-
cel or operation, the substances of the feed-lobes, or other
parts that answer the fame purpose, of course undergo a con-
iderable change, an additional proportion of the fame prin-
ciple entering into their composition, while a portion of their
carbon is difipated and destroyed: that by this alteration in
the proportion of their constituent principles and parts, the
faccharine fermentation is induced to take place, and fugar is
formed, as demonstrated in the operation of malting grain:
and that the fugar and carbonic acid, from their being more
fuble in water than in the oyd of faraneous matter, easily
combine with the moisture in the capillary vesfels of the
feed or other substances, and find a ready paflage to the
germ; the vegetative principle being thus brought into
action by a fimumus fputed to the particular nature of it:
and that by the decomposition of the feed-lobes, or other
parts, a nutritious fluid being thus formed and distributed
through the infant plant, its organs are excited to exert
their peculiar specific actions in decouping the nour-
ishment conveyed to them, and in forming new oxys from
the elementary principles of it, in order to the increase and
evolution of the vesfels and fibres.

As it is in this manner that the first stage of germination
or vegetation is suppozed to commence, it would appear
that in such feeds and fets, in order to their undergoing
these different changes the most readily, and in the most perfec-
t manner, on which, probably, healthy growth may ma-
terially depend, they should only be properly deposited
in the earth or soil, but, in the cafe of grain and feeds, be
so well ripened and filled with faraneous or mealy matter,
and possess such a degree of moisture, as may difpose them
to undergo such changes in a suitably fpedia manner;
while, at the fame time, a due supply of proper nutritious
matter is afforded for the perfect germination and early
growth of the infant vegetables or plants. They should
not consequently be put too deep in the ground as to be too
much excluded from the action of the air, or be fown or
feit when in too dry a condition from the state of the feafon
or other caufes, but be conffantly fuffered to have as much of
the agency and influence of fuch forwarding powers as
may be neceffary for the perfect vegetation and growth of
the plants or crops.

Others conclude on the grounds, and for the reafons that
are flated below, that two of the airs of which the atmo-
sphere is compounded, are absolutely neceffary to the
nourishment and proper growth of vegetables; those of vital
air or oxygen, and mephitic air or azote. It is found from
different trials, that plants placed in vital or oxygen air grow
larger, become more powerful, and are greener than those
put in that of the atmefpheric kind. That if the feeds of
the kidney-bean and the pea be put into earth of the fili-
ceous kind, and be fprinkled with water mixed with a small
portion of the oxygenated muriatic acid, in which oxygen
the most abounds and the most loosely adheres, they ger-
minate much sooner than if sprinkled with pure water:
but that if seeds be immerfed in diluted muriatic acid, they
become black and rugeous, and never germinate. That in no
kind of air deprived of oxygen do plants vegetate; for
if they be placed in azotic or mephitic air, in carbonic or
fixed air, they become faffed and drooping, it is faid, by
the heat of the fun, and gradually die away. And that in
nitrous air, plants become inactive in a few hours. It would
appear from this, it is thought, that the portion of vital or
oxygen air imports a natural stimulus, which is highly ne-
ceffary to excite the fibres and fustain the living power and
strength of the vessels of plants; and that, laftly, this air,
with the peculiar acidiflable bases, generates the various
acids which are found in plants or vegetables.

As the gluten of the fibres of vegetables confifts of car-
bon, chemically combined with azote, it follows, it is sup-
pozed, that the azotic air is abforbed or taken up by
the plants; and that it is by this means that vegetables in-
crease fo rapidly in rich foids, cemeteries, and other places
where animal and vegetable matters putrefy and decay in
large quantities in or on the ground.

Carbonic air too dissolved in water is absolutely ne-
ceffary to the vegetation of plants in order to provide their
carbonic principle, which is a conftituent part of the fibres,
oil, mucilage, and other vegetable principles.

It is fuggested, that plants appear to derive their caloric
or matter of heat from the surrounding atmefpheric air.
Hence it is that the flies of trees are fo cool; and that
nothing is more healthy for almost all plants in their vegeta-
tion and growth, than mild tepid flowers, by which they
obtain water together with this principle. That, laftly, feeds
do not vegetate in the cold, and many plants die in it.
Heat too is evidently of much benefit in vegetation, as giving
the natural colour to the foliage, flowers, and fruits of plants,
aeftuating or promoting the flow and circulation of the fap-
juice, increasing the faccharine matter, and promoting the
flavour of mott forts of fruit.

Light too contributes to the life and healthy growth of
plants; for those which vegetate in atmefpheric air de-
prived of its light, as in the night and dark places, become
dead and weak; but in the day-time, strong and coloured.

The
VEGETATION.

The rays of light, likewise, appear to contribute to stimulate plants, with the various gales or vapours they absorb and take up from the air.

Pure air has also been found by many to be essential to the production of perfect feeds, pulse, grain, and fruit, and that by its action upon or being taken up by the foil, it has very powerful and beneficial effects in promoting vegetation and the perfect growth of plants and crops.

Thus water, air, and these other matters, appear to have a very great share in the vegetation and nourishment of vegetables, but especially the two former. The first has been considered as indispensably necessary to the processes, and as supplying the principal materials of vegetable juices. It is unquestionably the chief medium through which the various nutritious matter derived from the soil, is conveyed to the plants which grow upon it. But it has been supposed more favourable to the vegetation and growth of grafted plants or crops than those of the grain kind; as crops of grains may be continually produced by watering, while with those of grain it has been found to be wholly impossible. It is found, however, that soft water, such as that of rivers, rain, or which has been exposed to the action of the sun for some time, is more favourable to vegetation, than such as is hard, as that of springs, or which is impregnated with metallic substances and other such matters. The author of Phytologia considers the first three things necessary to the infant vegetation and growth of plants to be heat, water, and air, as furnishing the general causes of fluidity, the menhirinum in which nutriment is conveyed, and the principle of excitability so perpetually necessary to all organic life.

However, besides these different matters, other agents are necessary, after the plants have been formed and evolved, to the perfect vegetation and growth of the crops, as those of earth or other such matters, which are not only useful and essential for the purpose of holding and supporting the plants in a steady and erect manner, but also for containing and conveying, at least, some portion of the food on which they live, as derived from the atmosphere or other sources, and for the regular ramification and extension of their fibrous roots, in order that it may be more certainly provided and supplied. They are beneficial too in receiving, retaining, and distributing moisture to them, as well as in receiving, reflecting, and dispersing the heat of the sun, dew, and exhalations of different kinds, by which their growth and perfection are greatly promoted. For though some plants of the aquatic kind grow in water, most of them have their roots in earth. Even marine plants, although they grow upon bare rocks or flores, are well known to be fixed to them, and that they derive their food from the seawater in or near which they exist. It has been contended by some that plants are actually nourished by earth alone, but numerous experiments shew the opinion to be erroneous, and that it is perhaps only the medium of their existence. It is well ascertained that they are capable of acquiring a great acception of weight, without almost any loss of weight of the earth in which they have been planted.

The air and affinities of dead organized materials are, likewise, requisite in the processes of vegetation and the growth of crops, as it would seem to be a part of the beautiful and orderly arrangement of Nature, that nothing should have life in vain, and that the destruction of one plant or animal should furnish food for others; consequently, that however useful air, water, light, heat, and earth may be to the growth of plants and crops, it is, if not certain, at least questionable, it is thought, whether they could ever come to perfection without the help of matter that had been formerly in an organized state. The richest soils, it is well known, are full of dead animal and vegetable matter, and there is no soil that will not produce plants or crops if a sufficient quantity of dead animal or vegetable substance be added to it. Under this denomination are comprehended all those manures which are found so useful in cultivation, more especially those to which some authors give the name of muriaticous, nitric, or nutritious. These substances and materials are greatly beneficial, by correcting the tenacity of stiff soils or lands, and the over-repotency of light ones, by producing a fermentation in them, and by affording nutritive matter to the roots of vegetables, as well as by retaining moisture in dry and expelling it in wet lands. Saline substances have been supposed too of much importance in vegetation by some, but they do not appear essential to the growth of any fort of plants except the marine; and there are many productive soils in which little or no saline matter can be discovered. Such matters may, however, be of use to vegetation, though not essential to it. That of common salt may operate upon plants as it does upon the human body, by afflicting to digest the food, without furnishing nutriment itself. It is of use, mixed with dung, as an affilant to putrefaction, and it may act in the same way in promoting vegetation. It is serviceable too by attracting moisture, destroying vermin in the soil, and decreasing and reducing the roots of any plants it may first meet with, thus furnishing nourishment to the succeeding ones.

It is found likewise, that the culture of the earth is essentially necessary for the vegetation and growth of plants and crops to perfection, the health and vigour of both the roots and branches being thereby greatly increased. By dividing and reducing the particles of soils, the roots of the plants and crops put into them can more easily and readily penetrate and spread out in them, as well as function in more expeditiously the nourishment which they contain. By proper and effectual culture too, such weeds or useless plants as are apt to rise, are extirpated and destroyed, whilst tilling the earth admits air and moisture more fully to the soils, and to those plants and crops the seeds orlets of which have been sown or put in them. It is evident likewise, that young trees thrive and succeed much better, if the soils in which they are planted have been previously ploughed in to deep a manner, as readily to admit their roots and suckers. Even after they are planted, it is supposed to be of great service to have potatoes and other such roots cultivated among the young trees in the plantations with a view to kill weeds, and loosen the foil for the free admission of air and water. And the practice seems to be generally well received, and to have much effect in promoting vegetation in most forts of vegetables.

The management of the farmer and gardener should, of course, aid and affil these views and intentions in every way as much as possible, in raising and producing plants and crops of different kinds; as by the suitable cultivation of the ground, the proper application of manure or other substances of that fort to it, the preservation of the moisture of it by different modes of cropping, and by every other practicable method in their power; as by such means the perfect vegetation and growth of them may be the best promoted and affil. See Following Land, Pulverization, Seed, &c.

It may be observed, that the substances or matters in land which have hitherto been found injurious to vegetation, are chiefly those of the metallic, sulphurous, aluminous, and alluring kinds. It has been noticed, that where mines of iron, lead, or copper, are near the surface, no plants will grow to perfection, as is well ascertained to be the case in different
different mining districts. Schistus too, in which there is generally a great deal of iron and alum, is found so unfavourable to vegetation, that any considerable quantity of it would destroy the fertility of the richest forts of land. The noxious, corroding, and weakening effects of such substances on the tender roots of vegetables being such in some cases as to cause their decay, dissolution, and destruction. Frequent flirring, or the exposure of new surfaces of land to the action of the air, and the use of lime, chalk, or other diluting matters, will, it is supposed, correct the injurious qualities of this substance, and promote the vegetation and growth of plants and crops in such states of land. The astringent principle or acidity in peat is often so great and so noxious to vegetation, that until any quality of that nature can be found, though that fort of land be a perfect mass of vegetable matter, nothing but heath and other such miserable plants are capable of growing in it. Vegetation is consequently in such cases only to be affixed by breaking the parts of the land well down, and the application of earthy and other matters to it, so as to wholly destroy its astringent property, and in fact change its nature. See Soil.

It may be noticed too, that the vegetation or growth of plants and crops is frequently much injured and impeded by the various sorts of vermin with which the earth as well as the air abounds. Thole which inhabit the earth, it has been supposed, may be destroyed and got quit of by the use of saline matters, lime, and other different substances, operations, and arts, as are seen under their several proper heads. See Grub, Mole, Slug, Worm, Vermin, &c. also Turnip.

But in regard to the myriads of thole of the infect kind with which the air abounds, it is more difficult and uncertain to propose or point out any remedy or means of prevention than to find one. It is not ascertained that the smell of any plant, in its natural growing state, is a destructive of infects; but there are several plants which are, when dried and reduced to powder, or when burnt near to certain insects, destructive of them, as thole of tobacco, hemlock, henbane, rue, wormwood, and others. Sometimes, however, vermin of this fort are occasioned by the weak stems and unhealthy growth of the plants, and the poverty of the soil of the land where they grow; the best remedies in such cases are, of course, thole of more perfect tillage and cultivation, so as to render them strong and healthy in their vegetation.

Vegetation, Artificial. Many of the processes and operations in chemistry afford productions, whether of fals or metals, or of whatever other substances, which very much resemble plants of one kind or other, whence they have been called metallic vegetation. But though many have been hence induced to believe, that these productions were formed in the manner of vegetables, there is not the least ground for such an opinion from reason or experiment.

M. Homberg, who has treated very accurately of the several kinds of these chemical vegetables, divides them into three different classes.

Thole of the first class are such as consist of a pure mafly metal, without the mixture of any foreign matter whatever. Thole of the second class are composed of a diffolved metal, which, though it has concreted afterwards, yet retains a part of the metal in it; and the third class contains thole which have no metal in them, but are merely composed of fals, oils, or earths, or of combinations of these.

All the productions of the first kind are made without the admixture of any liquor, and are merely owing to the force of fire. These are of a firm and solid texture, and may be taken out of the vesseles in which they were made, without danger of breaking them. On the other hand, the vegetations of the second kind are all formed in a fluid, and are all so brittle, that they are not to be touched without breaking. Of the third kind, some are formed, or will fusifi at least, in the dry air; others are very tender, and are formed only in fluids, the very flirring about which of itself destroys them. See Arbor.

Vegetation of Salts, a name given by M. Petit of the Academy of Paris, to the concretions which falls form, after solution in water, when let in the air to evaporate.

These concretions always appear round the surface of the liquor, affixed to the sides of the vessele, or arising above its top, and are very different in the different falls, and in most of them very beautiful.

One of the most ready and most beautiful of all the saline vegetations, is that formed by a solution of the falls in the caput mortuum of aquafortis with common water. If a pint of water be put to half a pound of this caput mortuum, and the whole boiled together, that the falls may be diffolved, and the liquor afterwards filtrated, and exposed in an earthen vessele, there will be formed, in about eight and forty hours, vegetations wholly like those from the mixture of spirit of nitre and oil of tar, except that those from the caput mortuum are more ramified and more beautiful. When the solution is exposed in a glass vessele, they form themselves on the surface into very beautiful figures of trees, shrubs, and bushes; and this not only on the surface, but on both the inside and outside of the glass. These can be compared to no known concretion, except to the vegetations of iron, described by M. Lemery; they differ indeed in nothing from these, but that the vegetations of the metal are of a brownish colour, whereas those of the fall are white. Sometimes, however, a beautiful such vegetation of the kind of alio, succeeds, it being formed in dry weather, in a moist season the vegetations form themselves more slowly, and are much less beautiful.

Glass vesseles are also essential to the vegetations being formed in their greatest beauty; they are never nearly so beautiful in earthen ones; and even in the former, the vegetations succeed much better in some sort of glasses than in others. The caput mortuum of aquafortis alio is very different, from the different diffutations; and all of it does not succeed alike in this vegetation of the fall. That which looks lightest, and of the reddest colour, seems the best for this purpose. An impregnation of this caput mortuum in red-wine produces no vegetations, but only forms a crust with small eminences on the sides of the vessele; and salkpetre, diffused in the impregnation of this caput mortuum in water, produces a much more beautiful vegetation than that of salkpetre alone; but at the same time much less beautiful than that of the impregnation alone. Salt-water, diffused in the same impregnation, sometimes will produce beautiful vegetations, but sometimes only a rough crust. Common rough salkpetre forms no vegetations, but only crusts over the vessele, as is the case with the solutions of many of the metals in different acid menfrums. And the same is the case in regard to many falls from which it might be natural to expect concretions of this kind. Memoirs Acad. Par. 1722.

VEGETIUS, FLAVIUS RENAETUS, in Biography, lived in the reign of the emperor Valentinian, to whom he dedicated his treatise "De Re Militari." Although he was probably a military man, his Latin style was pure, considering the age in which he lived. The best editions of his work are the Variorum, Leyd. 1644, and Vefal. 1670. Turpin's Commentary was printed in French, Paris 1783, in vol. 4. A work
A work on the veterinary art, by a writer of the same name, is printed with the “Scriptores Rei Rutilicae.” Moreri. Gen. Biog.

VEGETO-ANIMAL Matter, in Agriculture, a term formerly applied to one of the principal constituent parts of the farina, meal, or flour of some vegetable seeds. It is found in the greatest proportion in grain, especially that of the wheat kind, existing in a flake of mechanical union or mixture with mucilage or starch. On cautiously washing wheaten flour in the form of paste, in a kneading manner, under a small stream of water, until the whole of the flarky matter be removed, this substance or material is found in an elastic, duehle, tenacious flake, but incapable of being dissolved in it. It has none or scarcely any tafle, readily draws out and contracts, and is of a whitish-grey colour. When fully drawn out, it extends to the length of about twenty times its diameter before it breaks, and appears as if composed of fibres placed beside each other, according to the direction in which it has been drawn. If the force ceases, it recovers its original form by its elasticity; when dry, it is semi-transparent, and somewhat resembles glue in its colour and appearance. If it be drawn out thin when first obtained, it may be dried by exposure to the air, and in that flake it has a polished surface, somewhat resembling that of animal membranes. If it be exposed to warmth and moisture while wet, it putsrefies like an animal subflance; it crackles, swells, and burns, exactly in the manner of a feather or piece of horn. By distillation it affords, like animal subflances, alkaline water, concrete volatile alkali, and an empyreumatic oil. Its coal is very difficultly incinerated, and does not afford fixed alkali. From these facts, it is said to be obvious, that it is a subflance totally different from all the others known to exist in vegetables, except albumen, which has lately been discovered in some of them, and in many of its characters resembles the fibrous part of the blood. It does not appear to exist in any considerable quantity in other farinaceous subflances, such as rye, barley, buck-wheat, rice, and others of the same kind. M. Berthollet, however, thinks that it contains phosphoric acid like animal matters, and that this is the reason of the difficulty with which it is incinerated; and the younger Rouille found a glutinous subflance in the seeds of plants analogous to that of wheat. It is now commonly called gluten, and said to become a brown colour by exposure to the air, to be very fuggibly soluble in water, and to differ from albumen in being infinitely less soluble in that fluid. When burnt, it affords similar products to that subflance, and probably differs very little from it in composition. It is found in a great number of plants. Proodt is said to have discovered it in acorns, chestnuts, horse-chefnut, apples, quinces, barley, rye, peas, and beans; likewise in the leaves of rye, cabbages, cresses, hemlock, borage, saffron, in the berries of the elder, and in the grape. It appears, it is said, to be one of the most nutritive of the vegetable subflances; and that wheat seems to owe its superiority to other grain, from the circumstance of its containing it in larger quantities.

In the work on the “Connection of Agriculture with Chemistry,” it is said that different kinds of grain contain mucilage or flarch, and this subflance in different proportions, and that the same kind of grain contains them in different quantities, according to the climate, season, and soil. But that good wheat generally contains two-fifths of animalized matter, and three-fifths of flarch. And that good and well-raised bread depends on flour containing a due admixture of these two subflances. Hence, it is thought, by mixing the flour of different kinds of wheat, better bread may at times be produced than from one sort only. Extensive benefits, too, may arise to the proceeds of brewing, distilling, and making of vinegar, by a mixture of the different sorts of grain; and to that of distilling, a further advantage would be derived by a mixture of different roots with the grain, such as potatoes, parsnips, carrots, and many others, if prepared in a proper manner.

VEGETO-MINERAL Water of Gourd, in Medicine. See Water of Lead.

VEGGIANI, in Geography, a town of the island of Forcici; 12 miles W. of Bonifacio.

VEGI, or Vegi, the names given by the Arabian physicians to the accours. These writers seem not to have been acquainted with the plant itself in its growing state, but only to have known that part of it which was used in medicine in their time; but the Greeks described the plant in some fort.

VEGIA, in Geography, a town of Africa; 45 miles W. of Tunis.

VEGIANO, a town of Naples, in Bashcalcia; 12 miles S. of Potenza.

VEGI0, Maffeio, in Geography, was born at Lodi in 1406, and studied at Milan and Pavia, manifesting in the former place an attachment to poetry, and in the latter directinng his attention to civil jurisprudence. He obtained some honorary and lucrative appointments under the popes Martin V., Eugenius IV., and Nicholas V. Highly respected and esteemed for his genius and learning, as well as for the sanctity of his life, he died in 1458. As a Latin poet, he composed with facility, but without being distinguished for elegance or purity. He began, in his early age, with profane poetry, composing, among other works, an additional book to Virgil's Aeneid; but after he entered into the priesthood, he confined himself to sacred subjects. The best of his works in this class, highly commended by Dupin, was his treatise "De Educandis Liberorum et Rurum Claris Moribus." His prose style is accounted elegant and polished for his time. Moreri. Gen. Biog.

VEGLENSKOI, in Geography, a town of Rusia, in the province of Ufing, on the Vim; 72 miles N.E. of Yarenk.

VEGLIA, an island in the gulf of Venice, near the coast of Dalmatia, about 50 miles in length, from 6 to 14 broad, and 90 in circumference, anciently called Curitza and Fulfin. In the decline of the Greek empire, it obtained the name of Recla, of which the present is a corruption. It is situated in the innermost part of the gulf of Quarnero, and separated from the continent by a small canal only. There are many harbours, but unfit for the reception of large vessels, on account of the storms by which they are agitated. Its soil is mountainous and rocky, towards the north Recla, but very fertile to the south, and the valleys are extremely fruitful. The greater part is covered with woods, which occasion a considerable trade in firewood. Agriculture is not so much attended to here as the culture of the vine, which produces excellent wine. The culture of silk is insignificant; the breeding of horses is more important. The breeding of sheep and goats is likewise considerable. The quarries produce a red spotted marble, not unlike that of Verona, which is much known by the name of Mandulista of Venice. This isle is inhabited by 17,600 souls. N. lat. 45° 16'; E. long. 14° 42'.

VEGLIA, a sea-port town, situated on the S.W. coast of the island so called, surrounded with walls and defended by a caile, in which the governor resides. It is the see of a bishop, suffragan of Zara, and contains about 3,600 inhabitants. N. lat. 45° 11'; E. long. 14° 38'.—Alfo, a town of Naples, in the province of Otranto; 15 miles S. of Brindisi. VEG-
VEGLIANA, a town of France, in the department of the Po, near the Little Doria, where the French obtained a victory over the Piedmontese and Spaniards, in the year 1670; 13 miles N. of Turin.

VEGLIONELLA, a town of Naples, in Basilicata; 20 miles S.S.W. of Turin.

VEGRE, a river of France, which runs into the Eure, near Yvry.

VEHAILEK, a town of Arabia, in the province of Nedaj; 70 miles S.W. of Jamama.

VEHICLE, Vehiculum, in its literal sense, signifies somewhat that carries, or bears a thing along. See Carriage, Wagon, Wheel, &c.

Thus, in Anatomy, the term is said to be the vehicle that conveys the globules of the blood.

In Pharmacy, any liquid serving to dilute another with, or to administer it in, more agreeable to a patient, is called a vehicle.

In Painting, vehicles denote certain fluids, which are added to colours, in order to give them an unequous consistence while used, that they may be laid on and spread properly, adhere to the grounds on which they are laid, acquire a proper degree of tenacity when dry, and defend them from being injured by accidents. The principal vehicles hitherto used are oils, water, spirit of wine, and turpentine. But as water and spirit of wine want the unequous consistence necessary for spreading the colours, and dry away totally without leaving any glutinous subfance to bind and fix such of the pigments as are of an earthy or incohering texture; gums, size, varnish, and other such viscid subfances have been superadded to supply their defects, and render them of a due consistence and body.

VEHNE, or Vene, in Geography, a river which rives in the biphopic of Munifter, and joins the Solte, near Stickhauen.

VEIA. See Veglia.

VEICAMA, a town of Spain, in the province of Guipuscoa; 12 miles from Tolofa.

VEIENTANA Gemma, in Natural History, the name of a gem described by Pliny, and said to be found in Italy; he says it was black, but surrounded with a circle of white: it was probably a stone of the came kind.

VEIER, in Geography, a town of Spain, in the province of Seville, near the Straits of Gibraltar; 9 miles S. of Medina Sidonia.

VEII, in Ancient Geography, a town of Italy, in Etruria, S. of the Falerin, but nearer the Tiber and Rome. This was a very ancient town, and very considerable on account of the wealth and the value of its inhabitants. Its original name was Veja, which was also, among the Olci, the name of one of those carriages in which they refided before they had houses. Its vicinity to Rome was one principal cause of its misfortunes; for the jealousy and envy of that city were excited by its opulence and prosperity. From the time of Romulus, the inhabitants of these rival towns contended. At length Veii was taken by Camillus, after a siege of ten years, in the year of Rome 356 or 357. The booty was very considerable; and part of it was lodged in the temple of the Python Apollo. It is a sufficient evidence of the eligible sitution of Veii, that after the capture of Rome by the Gauls, it was a subject of deliberation whether this town should not be made the capital of the republic.

VEIL, Velum, a piece of stuff, serving to hide or prevent the light of any thing.

In this sense, we read of a large veil, or curtain, in the temple of Jerusalem, miraculously rent at the passion of our Saviour. In the Roman churches, in time of Lent, they have veils, or curtains, over the altar, crucifix, images of the saints, &c.

VEI is also used for a large piece of crape, worn on the head by nuns, as the badge of their profession. Whence, to take the veil, signifies to commence religious.

The novices wear white veils; and those who have made the vows, black ones.

The prelate before whom the vows are made, blesses the veil, and gives it to the religious.

VEIL, in Botany, see CALYXTRA. These terms are now exclusively appropriated to the membranous covering of the germen in Musci and Hepatische, through the summit of which impregnation takes place, and which therefore must be considered as a peculiar organ, partly perhaps, but not exactly, analogous to a corolla. It is elevated with the ripening capsule in Mufci, but splits irregularly, to let the fruit pails, in Hepaticae. The reader is required to correct two important errors of the press in the 8th column of the article MUCI: line 18th, for jinks, read jibanks; line 60th, for sexual, read sexual.

VEIL, CHARLES MARIE DE, in Biography, the son of a Jew at Metz, and a profelyte to the Roman Catholic religion by Boiflet, became a monk of the Augustin line, and entered among the canons-regular of St. Genievre. Pursuing his theological studies at Angers, he took the degree of doctor in theology, and taught in the public schools. In 1679 he visited England, and abjuring Popery, conformed to the English church. He had previously distinguished himself by his feriptual researches, and published Latin commentaries on the gospels of St. Matthew and St. Mark, on Joel, and the Canticles. During his stay in England he addressed a letter to Mr. Boyle, the design of which was to prove, against Father Simon, that the Scripture is the only rule of faith. In London he reprinted his commentary on the Canticles, giving a literal explanation of that book; and he also published commentaries on the twelve minor prophets, and on the Acts of the Apostles. At this time he styled himself a prebyter of the English church, but in conquence of marrying the daughter of a Baptist, he became connected with perons of that persuasion, and preached among them in the year 1685. His death is supposed to have happened about the close of the century.

The brother of the preceding, LOUIS DE COMPIEGNE DE VEIL, was also a converted Jew, and distinguished for his knowledge of Hebrew literature. He was interpreter of Oriental languages to the king of France, when he accompanied his brother to England, and joined in communion with the English church. The principal works he published were " The Jewish Catechism of Abraham Jagel;" a Latin translation, with notes, of " Maimonides de Sacrificis," and also of Abarbanel's "Exordium in Leviticum." Moreri. Gen. Biog.

VEILLANE, in Geography. See Veglana.

VELLLY, or Vesley, a town of France, in the department of the Aine, on the Aine; 9 miles E. of Soifons.

VEIN, in Anatomy, the name of those veiels which convey back to the heart the blood carried out from it by the arteries. All the details relating to the structure of these tubes, to their arrangement in the body, and to their office in the circulating fluid, are considered in the articles Heart and Circulation.

The veins are naturally arranged in three divisions: viz. the general venous systenl, commencing from the capillaries all over the body, and pouring the black blood into the heart by three large trunks: 2dly, the pulmonary veins, which
which are concerned only in the minor circulation: and gaily, the fyllem of the vena portarum, in which the blood that has circulated through the organs of digestion is conveyed to the liver, and distributed through the substance of that organ. The umbilical venous fyllem of the foetus, with its ramifications in the placenta, its trunk in the umbilical chord, and its subsequent course and distribution in the liver, is not included under either of these divisons. It belongs to the feta! state of exisfence, and is described under Embryo.

On the subject of the pulmonary veins, we have nothing to add here to what is Stated in the articles LUNG, CIRCULATION, and HEART: the vena portarum is described under LIVER; and the peculiarities of arrangement, belonging to the veins of any organs, are noticed in the account of those organs: so that the present article will include fimpily a description of the situation and course of the veins of the general syfem. These we shall trace, according to the course of the blood in them, from the branches to the trunks; as, on the fame principle, the arteries have been traced from the trunks to the branches.

The veins of the general syfem may be arranged in three divisions, according to the great trunks which terminate in the right auricle: viz. the cardiac veins, those belonging to the superior, and thofe to the inferior vena cava.

I. The veins of the heart do not all end in one trunk: besides one large vein, there are fome smaller. The great coronary vein of the heart (grande veine cardiaque polferiere) runs in the groove between the left auricle and ventricile; and opens on the left of, and below the folia ovaha and valvula Euflachii, in the right auricle. A middle coronary vein runs in the inferior flat surface of the heart, between the two ventricles, to open by a common orifice with the former, or close to it. At this opening into the auricle, a valve is placed, diferring confiderably in fize and appearance; sometimes filamentous and broad, covering the whole aperture, at other times smaller and hardly diftinguifhable; fometimes perforated or reticulated. See Heart.

Some fmalier veins open by one or more trunks in the anterior part of the right auricle. See the plates of Senac, fur la Structure du Coeur, &c. on these veins.

II. The superior vena cava receives the veins of the head, neck, thorax, and upper extremities.

The superfical veins of the head and face end for the most part in two trunks, an anterior and a posterior.

The anterior facial vein (fronfalen or angular) commences on the forehead, runs along the inner angle of the eye, and then pursues its course obliquely along the face from the corner of the eye to the base of the jawbone, which it passes at the fame point with the external maxillary artery. It joins, behind the angle of the jaw, the trunk of the posterior vein. This anterior facial vein, which is a large and very confluent trunk, receives a vast number of venous ramifications from all parts of the forehead and face, which are conveyed by one univerfal vena net-work or plexus. (See two excellent plates by Walter, Observat. Anat. 1775.) The following are enumerated as the vellfes which open into it: 1, vena frontales; 2, v. supra orbitalis; 3, 4, v. dorsalis nafl, superior and inferior; 5, palpebralis inferior interna; 6, 7, alaris nafl, superior and inferior; 8, palpebralis inferior externa; 9, 10, labiales superiores; 11, 12, two from the zygomatici and levator labii superiors; 13, ramus profundus vena facialis interna, formed by the junction of a vena ophthalonica facialis, which, communicating by its opposite end with the cavernous sinus, receives branches from some parts in the orbit; b. naflis posterior interna; c. alveolaris superior; d. veins of the buccinator, &c.; 14, labialis media; 15, 16, vena labii inferioris, superior and inferior; 17, 18, buccalis, superior and inferior; 19, 20, three, or four vena maffeterice; 21, submentalis; 22, glandulae faciei, &c.
taching the skull-cap. But the principal veins it receives come from the superior or convex surface of the hemispheres. These are spread irregularly over the convexities, advance from the fides towards the middle, uniting into larger and larger trunks, and open in considerable numbers on each side of the sinus: they receive the veins from the opposed flat surfaces of the hemispheres. The anterior branches are the smallest; the middle and posterior are much larger. They are directed at their termination obliquely from behind forwards, and sometimes pass for half an inch, in the substance of the coats, before they open.

The two lateral sinusæ, right and left (sinus transversi), are produced by the division of the superior longitudinal at the internal occipital protuberance. They are usually of equal size, but sometimes differ in this respect, the right being often larger. They proceed along the internal transverse ridge of the occiput, at the posterior attachment of the tentorium, as far as the commencement of the petrous portion of the temporal bone, when they descend along the internal surface of the mastoid portion of that bone to the foramen lacerum in bâti cranii, through which they quit the skull, taking the name of the internal jugular veins. These sinusæ are as large as the termination of the superior longitudinal; and are generally uniform on the internal surface. The cavity is triangular, where it occupies the posterior attachment of the tentorium: the base of the triangle being turned backwards, and corresponding to the skull, and the two fides being inclined towards each other, and joining at an acute angle in the tentorium. Where it lies in the mastoid portion, it confids of a layer of membrane lining the bony channel and another paffing directly over it.

The lateral sinus receives veins from the back of the cerebrum and cerebellum, and some meningeal veins; large branches from the integuments of the skull through the mastoid foramina, and from the muscles of the neck through the posterior condylid holes; veins from the cavity of the tympanum, according to Soemmerring; the superior and inferior petrous sinusæ; and the occipital sinusæ.

At the under or concave edge of the falx, there is found the inferior longitudinal sinus (falciiformis inferior). This is very small, just admitting a probe, and it opens behind into the following: it may rather be regarded as a vein than a sinus.

The fourth sinus (perpendicularis, torcular Herophili, sinus droit) is placed at the junction of the falx and tentorium, has a triangular figure, the bases being formed by the tentorium, and the sides by two oblique layers of the falx, and exhibits internally several prominent fibrous fasciculi. In fize it is about equal to a goose-quill. It receives in front the small vein called the inferior longitudinal sinus, and a large vein, called vena magna Galeni, which brings back the blood from the choroidplexuses and interior of the ventricles: it also receives, at its under surface, the superior veins of the cerebellum. It opens behind into the bifurcation of the superior longitudinal sinus; sometimes having a double termination.

The superior petrous sinus runs along the sharp ridge of the petrous portion, at the attachment of the tentorium, and opens into the lateral, just where that begins to descend from the tentorium. Besides some small meningeal veins, it has some from the anterior lobe of the cerebrum, and from the cerebellum.

The inferior petrous sinus is larger than the preceding, and runs in the junction of the bifairy processes of the occipital bone and the petrous portion of the temporal. Its anterior end joins the cavernous sinus, while the posterior opens into the lateral sinus, just before it enters the foramen lacerum. The right and left are united by one or more transverse communications on the basiary procys. This transverse communication unites the two inferior petrous sinusæ just where they communicate with the cavernous: it is placed at the anterior end of the basiary procys, is broad, and is defended by Bichat to contain the fame kind of cellular substance as the cavernous sinus.

The cavernous sinus is a large, complicated, and altogether the most remarkable of the cerebral sinusæ. It occupies the side of the sphenoid bone, reaching behind to the fissure which separates the end of the petrous portion from the sphenoid, and in front to the foramen lacerum: above, to the summits of the clinoide processes, and below, to the openings through which the nerves of the fifth pair pass. The dura mater, in this situation, is divided into two layers, one of which adheres to the bone, as in other situations, and forms the internal side of the sinus; the other, which is much thicker, forms its external side, and is part of the internal surface of the cranial cavity. In this latter layer the nerves of the third, fourth, and fifth pairs are placed, contained in sheaths of the membrane. The interval of the two layers is occupied by a soft kind of filamentous cellular substance, through which the nerve of the fifth pair and the internal carotid artery pass. The opthalmic veins, returning the blood from the orbit, opens into this sinus, which receives also meningeal veins, and communicates with the veins on the side of the basci cranii.

The cavernous is the most complicated of its structure, and altogether the most remarkable of the cerebral sinusæ.

The circular sinus is a small one occupying the superior aperture of the sella Turcica, and describing a circular course round the edge of the pituitary gland. It communicates on each side with the cavernous; and it receives veins from the dura mater and the pituitary gland. The anterior or posterior semicircle, or even the whole sinus, is sometimes wanting.

Occipital Sinusae.—These are very small; they begin at the sides of the foramen magnum, run backwards and upwards, and open into the lateral sinusæ close to their origin. Anterior occipital sinusæ are described, communicating with the inferior petrof and the cavernous, and opening into the lateral near its exit from the head: they are not confluent.

For representations of the veins and sinusæ of the brain, see Haller, Icon. Anat. falce. 1 ; Vie d'Azyr, Traité d'Anat. et Physiol. avec des pl. color. pl. 33. 35. 36. Santorini, Tab. Photium. 3.

The meningeal veins, or veins of the dura mater, receiving innumerable ramifications from the surface of the cranium, form trunks, which accompany the arteries, and often on each side, being lodged with them in bony channels of the skull: these veins open into the sinusæ, particularly towards the basis of the skull, and they are said to communicate with the pterygoid veins.

Veins of the Eye.—(See Walter, Epipola Anatomica de Venis Oculi.)—The vena ophthalmica cerebralís begins about the internal canthus, communicating with the ophthalmica facialis, goes outwards and downwards behind the globe, and ends in the cavernous sinus. The following veins enter it; viz. vena nafalis, ethmoidalis anterior, infraorbitalis, ciliaris interna, ciliaris superior, lacrymalis, ciliaris posterior, ciliares longae, ethmoidalis posterior, centralis retinae. The arrangement and distribution of these veselís in the eye are described under Eye.

There are free communications between the external and internal veins of the head, in various situations, which have been already noticed; viz. at the parietal, the mastoid, and the
the posterior condyloid foramina. The veins of the orbit also constitute a communication between these two sets of veins, as they are connected on one side with the facial veins, and on the other with the cavernous sinus.

It appears from the preceding description, that all the sinuses end, either mediately or immediately, in the right and left lateral, and consequently that all the blood conveyed to the brain is returned by these veins. Having passed the foramen lacerum, the tube is called the internal jugular vein; it swells out into a dilatation received into the fossa jugularis of the temporal bone, descends perpendicularly along the neck, in company with, and on the outside of the internal carotid first, and, afterwards of the common carotid artery, and of the par vagum, with which parts it is encased in a common cellular sheath. Just behind the anterior extremity of the first rib it ends, by joining at a right angle the subclavian vein. The internal jugular is a very large vein; when diffused in the living subject, or by injection after death, it is nearly as large as the thumb. It receives the following veins; viz. the pharyngeal, the lingual, the common trunk formed by the union of the anterior and posterior facial, the suprarenal, and middle thyroid.

The external or superficial jugular vein is formed by two or three principal trunks, and by smaller branches, which form a kind of venous plexus on the side of the neck, covered by the skin and by the latissimus collae. These trunks are the occipitalis superficialis, which commences, in company with the occipital artery, from the integuments of the back of the head, and receives branches from the muscles of the neck; transversa collae, which accompanies the artery of the same name: deep-seated veins of the cervical muscles; subcutaneous veins towards the front of the neck; and smaller twigs from the flerino-nalfoideus and lymphatic glands. The trunk terminates at the angle of union of the internal jugular and subclavian, or in the subclavian itself. For the veins of the neck, see Walter's plates in the Observat. Anat. already quoted.

Veins of the Upper Extremities.—The arteries are every where accompanied by corresponding veins, which lie close to them, and are generally double, one on each side. These it is not necessary to describe. In addition to these, which may be called the deep-seated, there is a cutaneous set of veins in the fingers, fore-arm, and arm, forming large trunks placed merely under the skin, not accompanied by any arteries. Both the deep-seated and cutaneous veins end in a single large trunk, the axillary, which accompanies the artery of the same name.

The superficial veins of the fore-arm lie between the skin and the fascia, and form a venous net-work, composed of larger and smaller branches, over the whole limb. There is great variety in the size and arrangement of the trunks, which, however, are regular and constant in the arm. The digital veins run into trunks at the backs of the fingers, completely covering them after successful injection; they form a plexus (dorfolis manus) on the back of the hand, from which a large trunk (cubitalis interna, or ulnaris superficialis) or two, with smaller ramifications, run in the course of the ulna to the elbow. It pales over the tendon of the biceps, and assumes the name of basilic vein; ascends along the arm, on the inner edge of that muscle, in company with the brachial vein, and enters the axilla, where it ends in the axillary vein.

A large vein on the back of the hand, arising from the little finger, was called by the ancients fetus. A venous plexus arises from the thumb, of which the largest branch is sometimes called cephalica pollicis: this Vol. XXXVI.

plexus, containing one or two larger trunks, (radialis externa, or cephalica minor,) is continued along the radial side of the fore-arm to the bend of the elbow, where it divides into two branches; the largest, under the name of median vein, passes obliquely in front of the joint to join the basilic vein; the other is called the cephalic, (cephalic major,) ascends on the outer edge of the biceps, runs in the cellular interval between the pectoralis major and deltoid to the edge of the clavicle, then dips under the bone, and ends in the axillary vein.

There is considerable variety in the median vein, which is sometimes merely an oblique communication between the basilic and cephalic: in other instances, a large branch comes from the middle of the fore-arm, (mediana communis,) and divides at the elbow into two trunks, which separate like the branches of the letter V, and join, one the basilic, and one the cephalic. These branches are then called vena mediana basilica, and mediana cephalica. There is always a large communication at the elbow, between this median vein and the radial and ulnar veins.

The axillary trunk, in which all the veins of the upper extremity end, is placed in front of its corresponding artery, on the side and anterior part of the chest; pales in front of the anterior sacleans muscle, then taking the name of subclavian, and ends at the extremity of the first rib, by joining the internal jugular at a right angle. In this angle the thoracic duct ends behind, on the left side; and the minor trunk in front, on the right side.

For representations of the veins of the upper extremity, see Camper, Demonstrationes Anatomico-Pathologicae, lib. 1. Klint de Nervis Brachii.

The axillary trunk receives the superior and inferior thoracic veins, the external and internal sceleular, the dorfolis sceleular, the vertebral, and the superior intercostal vein.

The trunk of the latter accompanies its corresponding artery in the transversa processes of the cervical vertebrae, commencing about the foramen magnum, and receiving numerous branches, of which the most remarkable are from a large plexus of veins lying close on the vertebrae before and behind, and connected with the transversa collae, the occipital, and the internal jugular veins, from the sinuses of the medulla s沿途nas in the neck, (circuli venosi cervicales medullæ s沿途nas,) and communicating with the cerebral veins, at the foramen magnum. The vertebral and superior intercostal veins end in that part of the trunk called subclavian.

The right superior intercostal is sometimes deficient; that is, the veins of the two or three superior intercostal intervals, instead of uniting into a separate trunk, join the vena azygos. The left is always a considerable vein, formed by the veins belonging to the five or six superior intervals, which join into a trunk ascending on the left side of the vertebral column, receiving the left bronchial vein, and some other small branches.

The subclavian vein, having received the internal jugular, descends on the right side almost perpendicularly, and on the right of the artery innominata, receives the internal mammary vein, and very soon receives the left subclavian at a right angle. It now takes the name of superior or descending vena cava, continues its course in the same direction, receives the vena azygos from behind, and after a farther perpendicular descent of about an inch, having penetrated the pericardium, terminates in the right auricle.

The left subclavian vein crosses the chest, immediately behind the upper edge of the first bone of the sternum, and in front of the trachea and primary branches of the
aortic arch, proceeding transversely from left to right, and joining the right subclavian above the pericardium, as already described. It receives in this course the left internal mammary, the median, thymic, superior pericardiac, and inferior thyroid veins.

The internal mammary vein accompanies the artery. The thymic veins are connected with the mediastinal, pericardiac, &c. They end either in the subclavian, internal mammary, bronchial, superior intercostal, or thyroid.

The superior and posterior pericardiac veins generally end in the subclavian; but they may terminate in the bronchial or internal mammary. The vein accompanying the left phrenic nerve ends in the bronchial; on the right side, in the internal mammary.

The vena azygos returns the blood from the parietes of the chest, except in so far as the superior intercostal veins are concerned, which, as we have already described, join the subclavian. This vein connects the superior and inferior veins of the body: for its inferior ramifications anastomose with the lumbar or other abdominal veins. Hence, where the inferior vena cava has been obstructed, the blood has found its way through the vena azygos into the superior.

The minute origins of the vena azygos on the right side of the body are connected with the vena cava, the lumbar, or the renal veins. The trunk, at this part small, enters the chest, either with the aorta, or through an interval in the right crus of the diaphragm. It ascends on the right side of the vertebral column, in front of the right intercostal arteries, covered by the pleura, with the trunk of the aorta on its left, and the thoracic duct in the cellular substance between it and that artery, receiving the intercostal veins, and increasing in size. About the third dorsal vertebra it quits the spine, passing forwards over the right bronchus and pulmonary artery, receiving the right bronchial and some axillary veins, and of a considerable size, and opens into the back of the superior vena cava.

The intercostal veins, which it receives in its course, accompany the arteries of the same name, and return the blood from the intercostal muscles, and those of the back, from the intercostal muscles, from the vertebra, pleura, intercostals, &c. The vena azygos receives a large branch from the left side, called the hemi-azygos. This begins by roots, which communicate with the abdominal veins, from a trunk entering the chest through the diaphragm, ascending on the left side of the chest, receiving four, five, or more left inferior intercostal veins, and then crossing to the right side, to join the trunk. Sometimes the hemi-azygos joins the common trunk by two or three branches; sometimes it is not formed, and the left intercostals proceed straight to the right side. See Würfberg, Observat. Anat. de Vena azyga duplici, aliique hujus vene varietatis. Goetting. 1778.

III. The inferior Vena Cava.—The veins of the lower extremities, of the pelvis, and the abdomen, terminate in this trunk.

The veins of the lower limb of the upper extremity, confluent of a deep-seated fat accompanying the arteries, and therefore not requiring a separate description; and a superficial order, covered only by the skin, and intervening between it and the fascia. The femoral vein is the common channel for the blood of both those systems of veins.

The superficial veins of the leg comprise two principal trunks, called the phrenes: there is indeed, as in the upper limb, a plexus covering nearly the whole of the foot and leg, of which the different branches every where communicate.

The phrenes externa or minor arises from the veins plexus of the sole and back of the foot towards the outer edge; it runs below and behind the outer ankle, then rises over the calf, and having frequently communicated with the deep-seated veins, terminates in the trunk of the popliteal.

The femoral vein passes under the crural arch, on the outside of the corresponding artery, and continues in company with the artery, under the name of the external iliac, along the side of the ploos magnus, until it meets with and joins the internal iliac or hypogastric vein from the pelvis, at the sacro-iliac joint, or the point where the common iliac artery bifurcates into its external and internal branches. Immediately above the crural arch, the external iliac receives the epigastric and circumflex iliac veins.

The internal iliac or hypogastric vein is made up by the union of venous trunks, corresponding to the various arteries which are given off from the internal iliac artery. These veins accompany their respective arteries; but they are remarkable for forming thick and intricate plexuses, which surround the prostate, vesical femorales, neck, and fundus of the bladder, urethra and vagina, and rectum.

A large vein runs along the back of the penis, in its middle, between the two arteries dorsales, and returns the blood from the glans, corpus spongiosum, bulb, and corpora cavernosa. It passes under the arch of the pubes, and divides into a right and left branch, which run into the plexus about the prostate and vesical femorales.

The superficial veins of the penis and scrotum find their way under the arch of the pubes, communicating with the internal pudic vessels, and end in the plexuses about the neck of the bladder.

They are united on the outside with branches of the femoral vein, and of the femoral. The prostate and vesical femorales, the lateral and inferior parts of the bladder, are covered by numerous ramifications of a dense plexus, from which the trunks of the vesical veins convey the blood to the hypogastric.

The veins in the labia are numerous, and communicate frequently: these and the veins of the clitoris pass under the arch of the pubes; the front of the vagina and urethra are covered by a thick plexus, which is the common termination of the external and internal pudic vessels. These plexuses envelope the sides of the vagina, the anterior, lateral, and inferior parts of the bladder, and end in the vesical veins.

The external hemorrhoidal veins end in the pudendal; the middle occupying a space of three or four inches, and united with the plexuses already mentioned, join the hypogastric. These latter then are interposed between the internal hemorrhoidal, which joins the vena portarum, and the external, from which the hemorrhoidal flux proceeds.

Large veins proceed from the vagina and uterus to the internal iliac: there are also the lateral facoral veins, corresponding in number to the facial foramina, out of which they proceed, and united with the middle facoral vein. The other vessels contributing to the hypogastric vein are, the obturatrix, ischiatic, pudenda communis, glutea, ileo lumbaris.

The primary or common iliacs, formed by the junction,
at nearly right angles, of the external and internal, are very
conflable venous trunks, differing lightly on the right
and left sides of the body. The right is much the shorter,
and proceeds obliquely behind, and rather above its cor-
responding artery. The left, placed behind and below the
left common iliac artery, proceeds obliquely upwards and
towards the right, across the front and upper part of the
faccrum; then goes between the fifth lumbar vertebra and the
right common iliac artery, to join its corresponding vein,
at an acute but open angle, on the right side of the vertebral
column, at the interval between the fourth and fifth lumbar
vertebrae; forming by this union the great trunk of the in-
terior or ascending vena cava.

One or two lumbar veins sometimes join the common iliac.
The facra media, a small vein, terminates, either at the
angle of union, or in the left common iliac.

The inferior vena cava lies at its origin, close to the aorta,
on its right, and on the right side of the vertebral column: it ascends in the same relative position, first con-
ected to the spine, then to the right crus of the diaphragm,
but more and more distant from the aorta, as it rises higher
in the body. It leaves the vertebral column towards the
upper part of the abdomen, and enters a deep sulcus in the
posterior or thick edge of the liver, which covers two-thirds,
and sometimes the whole vein. From the joints upwards the
size of the trunk is considerably increased: it will easily ad-
mits a large thumb. Quitting the liver, it penetrates the
tendon of the diaphragm (see DIAPHRAGM), and imme-
diately opens into the right auricle of the heart. (See Heart.) In its passage it receives the following veins.

1. The facra media has already been mentioned.
2. The lumbar veins correspond to the arteries of the
same name, and return the blood from the parts supplied by
those vessels. They form about four trunks on each side,
which end in the lateral and posterior part of the inferior
cava.

3. The splanchnic veins. They come from the vessels in
the male subject, from the uterus and ovaria in the female;
receive various branches from the ureter (ureterice), fat of
the kidney (adipofe), &c. and communicate with veins in the
mesentery and mesocolon; form first a considerable
plexus, with several trunks communicating together, and
afterwards a single vein, which ends in the front of the vena
cava on the right side, and in the renal vein on the left.

4. Renal or emollient veins. Of these large trunks, the
right is much shorter than the left, on account of the re-
ative position of the vena cava and the kidneys. The latter
crosses the vertebral column in front of the aorta. There
are rarely more than one on each side.

5. Capillary veins. These often end in the renal, par-
cially on the left side, otherwise they terminate in the cava.
6. Hepatic veins. They are numerous, and of different
sizes. Usually there are from three to five large ones, and
several smaller. They return the blood of the vena portae
and that of the hepatic artery.

7. Inferior diaphragmatic veins; accompanying the ar-
teries, and ending either in the cava, or in an hepatic vein.
Soemmering rates that some diaphragmatic veins join the
vena portae.

Besides the works to which we have referred in the course
of this article, for plates illustrating particular veins, we
may refer in general to the Fasciculi of Haller, to the plates
of the veins in Loder's collection, and to Mayer's Anatomische
Befchreibung der Blutgefässe des menschlichen Körpers;
mit kupfern, 1788, 8vo. See also Walter Angiologisches
Handbuch, 1779. Soemmering, De Corporis Humani
Fabrica, t. 5. Bichat's Anatomie Descriptif, t. 4.

VEINS, Disposés of the. Veins (says Mr. Hodgson) are
liable to all those morbid changes which are common to soft
parts in general; but the membranous lining of these vessels
is peculiarly susceptible of inflammation. When a vein is
wounded, the inflammation, which is the effect of the injury,
sometimes extends along the lining of the vessel into the prin-
cipal venous trunks, and, in some instances, even to the
membrane which lines the cavities of the heart. This inflam-
mation sometimes produces an effusion of coagulating lymph,
by which the opposite sides of the vein are united so as to
obliterate the tube. In this manner, a great extent of the
vein is occasionally converted into a solid cord. In some in-
stances, the secretion of pus into the cavity of the vein is
the consequence of inflammation of the membranous lining
of veins: under these circumstances, the matter is either
mixed with the circulating blood, or the inflammation, having
produced adhesion of the sides of the vein at certain inter-
vals, boundaries are formed to the collections of pus, which
in this manner form a chain of abscesses in the course of the
vein.

When the inflammation of veins is not very extensive, its
symptoms are the same as those of local inflammation in gen-
eral; but when the inflammation extends into the principal
vein, the trunks, and pus is secreted into the vessel, it is
accompanyied with a high degree of constitutional irritation,
and with symptoms which bear a striking resemblance to
those of typhus fever. See Hodgson's Treatise on the Dis-
exes of Arteries and Veins, p. 511, 512.

In the first volume of the Transactions of a Society for
the Improvement of Medical and Chirurgical Knowledge,
Mr. Hunter has published an extremely interesting paper on
the subject of inflammation of veins, and he has particularlyad-
verted to that common cafe, an inflamed arm after bleeding.
By force, he observes, this complaint has been imputed to the
wounding of a tendon; by force, to the injury of a nerve;
and by others it has been ascribed to a bad constitution.

Mr. Hunter expresses his doubts of the accuracy of these
opinions, and he remarks, that the manner in which these
fore arms come on, plainly proves that they arise from the
wound not healing by the first intention; for, in most
cases, the external wound first fettles or inflames, and
then suppures or ulcerates, the cavity of the vein be-
coming subfrequently impervious. In some instances, this
suppuration is only superficial, the vein and parts below
having united. In other examples, the skin appears to be
united, but not close to the vein, so that a small ab-
seces forms between the vessel and the integuments. This
burst and discharges a thin watery fluid, and no further
mischief happens. When, however, this imperfection of
union is continued on to the cavity of the vein, this vessel
inflames both upwards and downwards, frequently in a con-
fiderable extent, and the surrounding parts join in the
inflammation.

We find, says Mr. Hunter, all these variations in different
cases. Sometimes the disease goes no further than an in-
flammation near the orifice of the vein, and the case often
ends in resolution. At other times, the inflammation is
carried further, but suppuration is prevented by the adher-
vie inflammation taking place in the affected portion of the
vein, and, in such cases, the veins may be plainly felt, like hard
cords, after the surrounding tumefaction has subsided. But
this salutary effect is not always produced; and suppuration
in the vein is the consequence, but often in fo limited a de-
gree, that only a small abscess forms in the cavity of the
vein, near the puncture. The confinement of the matter in
this part of the vein, arises from adhesions in the vessel, a
little above and below the orifice. But, in many cases,
adhesions do not occur; and then the inflammation and suppuration are not confined to the vicinity of the wound. On the contrary, an abscess is frequently produced, occupying a considerable length of the vein in both directions; and, says Mr. Hunter, we often have more than one abscess; nay, sometimes there is a series of them, generally in the direction towards the heart; but not always in this course; for, occasionally, these abscesses are observed between the orifice in the vein and the extreme part of the limb.

In consequence of a wound in the foot, Mr. Hunter saw the vena saphena inflamed all up the leg and thigh, nearly as high as the groin; and he was obliged to open a chain of abscesses, which reached nearly the whole course of the vessel.

In cases in which the inflammation had been violent, and in which the opportunity of examination was afforded, Mr. Hunter found the inflammation at some distance from this violence in the adhesive state; in some places, the sides of the vein were adhering; and, in others, the inner surface of the veins was covered with coagulable lymph. When different abscesses had formed, he always found, that the spaces of the vein between them had united by the adhesive inflammation, and it is this union which circumferes such abscesses.

In examining the arm of a man who died at St. George's hospital, Mr. Hunter found the veins, both above and below the orifice, united in many places by the adhesive inflammation. He also found in many parts of the veins the commencement of suppuration, without ulceration having actually begun; while, in several other places, ulceration had occurred, and destroyed the surface of the vessel next the skin, a circumfered abscess being produced. The vein near the axilla was in a state of suppuration; and as no abscesses were formed beyond the part affected, Mr. Hunter conceived that the matter had palled freely into the circulation, and most probably been the occasion of the man's death.

When larger abscesses had come on than those arising from the ulceration of the wound of the lanceet, Mr. Hunter always found that the vein was afterwards obliterated, having united and healed up as any other cavity does, so that the patient could never be bled in the same vein again.

Inflammation of a vein is a common effect after bleeding horses, which is to be ascribed to the careles and rough manner of closing the puncture with a pin. Mr. Hunter has seen the jugular veins of horses inflamed through their whole course, the swelling extending to all the side of the head, and the inflammation reaching even to the 'cheek. In these cases there is always an abscess formed at the wound, and often several along the vein, as in the human subfeet; and whenever the complaint is carried as far as this stage, the vein is rendered for ever afterwards impervious. Many horses die of this disease; but what is the particular circumstance which occasions their death, Mr. Hunter was not able to determine. It may (says he) either be that the inflammation extends itself to the heart, or that the matter secreted from the inside of the vein passes along that tube in considerable quantity to the heart, and mixes with the blood.

Although the operation of venesection, which is the most frequent cause of this complaint, is to appearance trifling, yet, as it is often of very serious consequence, both to the life of the patient and the character of the surgeon, the operator should use the utmost care to prevent an evil of such magnitude. He should be particularly attentive to the mode of closing the wound and binding up the arm. This is to be done by bringing the two sides of the wound togeth-
rather than veins, are most apparent in the calyx of many plants.

Veins, Metallic and Mineral, in Geology, are fissures intersecting rocks or strata, filled more or less completely with mineral or metallic matter, different from the substance of the rock. When veins are seen on the surface intersecting or traversing a mountain, they have been supposed to resemble the veins of animals; but the resemblance is only superficial, for veins are not tubular, except in a few instances; but their thickness is small, compared with their length and depth.

Metallic veins are the principal repositories of most of the metals, except iron and manganese, which occur more frequently and abundantly in beds than in veins. The thickness of metallic veins varies from a few inches to several feet or yards: the same vein varies also in thickness in different parts of its course, sometimes contracting to a narrow finger of ore, and then expanding again to the width of several yards. The depth to which they descend is unknown, for we believe no instance has occurred of a considerable vein being worked out in depth, though it may sink too deep to render the operation of the miner profitable; or it may branch off in a number of branches, which are too much intermingled with the rock to be worked to advantage. In cases where the metallic ores have disappeared at considerable depths, the veins are still continued, though they are filled exclusively with the mineral matter or vein-flone which accompanied the ore in the upper part of the rock. Some veins appear to grow wider, and others to contract as they descend. The direction of veins downwards inclines more or less from the perpendicular; but they sometimes run for a certain distance parallel with the dip of the beds or strata in a mountain, and then strike down through the lower beds.

The length of metallic veins has rarely, if ever, been accurately determined; they have frequently been traced several miles, but their further progress has been concealed by the intervention of valleys, rivers, or accumulations of sand and alluvial deposits. Some of the metallic veins in South America have been traced to the distance of eighty miles. Large veins generally take a nearly direct line through a country, except where they are turned aside by cross veins, or what are called in Cornwall cross courses; it is also remarkable, that the metallic veins in England generally run nearly east and west, and the cross courses north and south. To what cause this is owing we are perfectly ignorant. Large metallic veins frequently send off smaller veins, or fingers of ore, from their sides, which penetrate the rock to a considerable distance on each side of the large vein. Veins are seldom entirely filled with ore, but sometimes it extends in a compact mass from one side to the other. More frequently, the ore is intermixed with mineral matter called vein-flone, matrix or gangue: this, according to the rock which it intersects, will be either calcareous fpar, fluor fpar, barytes or quartz. The vein-flone and the ore are frequently arranged over each other, lining the sides of the vein with alternate layers of metallic and mineral matter, and filling up the whole vein. In the mines of Cornwall, the ores of copper and tin commonly occur in detached masses, which are called bunches of ore; and the other parts of the vein, being unproductive, are called deads.

The vein is generally separated from the rock which it intersects by a thin layer of mineral matter distinct from the vein, and from the rock itself, and also by a thin lining of clay. Sometimes there are large cavities in veins called drafets, which are generally lined with crystals. In other instances the vein divides, including a piece of rock, which is called the rider; but it is observed, that the inelosed masses, or riders, differ in its quality from that of the rock through which the vein passes.

The superficial part of a vein generally contains the ore in a decomposing state; and it frequently happens that the ores in the upper and lower part of the vein are different: thus in Cornwall, blende, or the sulphuret of zinc, often occupies the uppermost part of the vein, to which succeeds tin-flone, and at a greater depth, copper pyrites. See Zinc, Tin-Stone, and Copper.

When Mr. Pryce wrote his "Mineralogia Cornubiana," the mines of Cornwall had not been worked to a great depth, for he says the richest flone of a mine for copper was from eighty to one hundred yards deep, and for tin, from forty to one hundred and twenty yards. This account by no means corresponds with the present state of the Cornish mines. The Doleouth copper-mine, near Redruth, is worked to the depth of four hundred and fifty-fix yards, and is very productive at that depth.

Veins generally decline from the perpendicular, and descend into the earth obliquely. The fides, or, as they are called, the walls or cheeks of the vein, are differently denominated, the upper side being called the hanging-fide, the up-check, or hanger; and the under side, the back-fide, the down-check, or the ledger. The veins we have been describing are called rake-veins in some parts of England, and in Cornwall, they are denominated bides; which see. These metallic veins have commonly the same direction, or nearly so, in the same district, and the veins which cross them are generally unproductive, or contain metallic ores of a different kind. They are called cros courses, or north and south veins.

Metalliferous rake-veins intersect most of the mountains called primary, such as granite, gneifs, and mica-flone. (See Granite, &c.) But they are more abundant in flat-rocks than in rocks of granite or porphyry. (See Granite, Slate, and Porphyry.) They also intersect the rocks of transition and mountain lime-flone, which rest upon flate, or alternate with it; but they rarely rise into the secondary strata which contains coal. This fact seems to prove that veins were formed prior to the deposition of the upper secondary strata. When a metallic vein in its descent passes through different kinds of rock, it is frequently observed that the products of the vein vary in each bed; and when it passes through regularly stratified beds of the same rock, there are particular strata in which the veins are always found most productive, and these in the north of England are called bearing measure. If the nature of the rock seems to have produced a change in the quality of the ore, it is in less remarkable that the rock itself is also frequently changed or decomposed in the immediate vicinity of a vein. This change is more apparent in some rocks than in others, particularly in granite, gneifs, gneifs, mica-flone, argillaceous schistus or slate, and porphyry. In such instances, according to Werner, it is only one of the component parts of the rock that is decomposed, either the feldspar, the hornblende, or the micas, but never the quartz. This change sometimes extends to a considerable distance of each side of the vein, even to a fathom or more; it extends farther in some places than in others, and is most general in those parts where the vein contains sulphur. Sometimes this change in the rock may be perceived so far, that it serves as a guide to the miner; and in following a fertile vein, when he comes to a place where the rock is decomposed, he concludes that the metallic ore will soon be found. In Cornwall, the feldspar is frequently changed in the vicinity of a vein, and tin-flone is sometimes differentiated through the rock to some distance on each side of it.
VEIN.

The crofs courses or veins which interfe6 the metalliferous veins, frequently occupy a considera6 ble a~ange­men in the po6ition of metalliferous veins, and, what is still more re­markable, occasion a change in the quantity or quality of their contents. When a vein is cut through by another, either in its line of bearing along a country, or crofes it by declining in a different direction, the vein which is cut through is superposed to be of more ancient formation than the vein which crofes and cuts through it; but it may be doubted, from various circumftances, whether many of these veins were not formed at the fame time with the rock itself, or were fffures paffing through the rock in different direc­tions, into which the various metallic fubftances were fer­ected, during its confolidation. To form a more difting­uifh idea of the structure of a vein and its interfe6 by crofs courses, we refer to Plate IV. Geology. Fig. 4, and a rep­resent a rake-vein defcending obliquely; b b, the rock; e, e, the walls or checks of the vein; d, an interpoing pie6e of rock, called the rider; e, e, the division of the vein into numerous small veins or ftrings of ore. If the fpae at d, which is superposed to be filled with rock, were empty, or filled with water, it would conftitute what is called a drufe; and it is in thes cayfies or drufes that all the moft beautiful and regular cryflallizations of the mine occur. Fig. 5, re­presents the fection of a vein containing a metallic vein through, and displaced by crofs courses or veins of another metal; aaa is a vein which appears to have been once con­tinuous, and contains tin; b b, b, represent different veins of copper, which cut through the former, and have upheaved the lower part, and brought them nearer the surface. In Plate II. Geology, fig. 10, re­presents the ground plan or horizontal fection of a plot of ground travefed by a vein and a crofs course; E. W. repre­fent the cafte and welf sides of the ground. It is in this direction the vein a a paffes, but it is cut through by the crofs vein b b, which has carried the welfer fide of the vein and the ground along the fide of the ftrata, to the north of its original position. Such a frafture and removal of the vein can only be conceived to have taken place by a lateral or horizontal motion of a portion of the ground. Such a motion has been frequently observed during violent earthquakes. For though the ground is heaved up­wards, the greater reftance which certain parts offer to this motion must occa6 a lateral pressure on other parts of the earth's surface, and to fuch a pressure we muft also refer the remarkable conftorions of the coal ftrata near Valenciennes. See Plate II. fig. 9.

Metallic veins frequently occa6 a displacement of the ftrata when they pafs through regularly ftratifed rocks; and it is ob­erved, that when this displacement is con­iderable, fo as to bring a bed of lime-flone on the fame level with a bed of fand-flone or slate, the vein is never fo produc­tive as when the oppofite fides or walls of the vein are in the fame kind of rock. See Plate II. Geology, fig. 8. where the different ftrata a, b, c, d, e, f, g, repre­fent different ftrata on each fide of a vein or fault. If d d, are sup­posed to reprefent parts of a vein or fault, the vein being broken by the vein, and g g a bed of fand-flone below the lime-flone, but brought on the fame level with it by the upheaving of the ftrata, in that part of the vein where the lime-flone, d, and the fand-flone, g, form the wall opposite to each other, the vein will be unproduc­tive, though in other parts of the district, when the vein paffes through the fame bed of lime-flone, on each fide of it, at the fame level, it will be remarkably produc­tive. These facts may be commonly ob­erved in the mining districts of the western parts of Northumberland and Durham, where the ftrata confi6 of different beds of mountain lime-flone, sand-flone, and slate. See Strata, under which article the fuccafion of the different beds is enumerated.

As crofs veins generally displace and injure the quality of veins, on the contrary, when cafte and weft veins in a district meet, by a flight variation in their direction or dip, the part where they join is frequently very rich in ore; and where a number of metallic veins crofs each other at the fame place, they frequently produce a large irregular conical mass of ore of vaf extent, from which the different veins diverge, like radii from a common centre. The main fhaft of such a vein, which Mr. Williams, in his Mineral Kingdom, calls an accumulated vein, "refembles," he fays, "the indi6 of a glafs-houfe; and the vaf capacity of this vein is frequently flored with a rich body of metallic ore, often imbedded in foft minerals fols; but the vein of this metal, where they join, diverge reftemile to the veins, or perpendicular mineral fffures. When the ore is worked out of an accumulated vein, it exhibits a frightful gulf, fomtimes fifty or fixty feet wide below, and is often worked down to a great depth from the surface." A number of thefe accumulated veins have been worked at Pike-Law, in the county of Durham. Crofs courses fometimes contain ore to a fmall distance from their junction with metallic veins, and in other situations they become fo rich as to be worked with advantage. The Botallock mine, on the sea-coaft near St. Juft, in Cornwall, offers a fhring illustration of this, though we believe its structure has not been generally known or understood. The vein which is worked is a north and fouth vein, varying in width from nine to twelve feet, and extending under the fea. The vein-flone is quartz, with a fmall quantity of flour fpar. It is found to contain ore of copper and tin in many parts where the cafte and weft veins enter it, and for thirty or forty fathom of the fea. This mine produces the richest ore of copper in Cornwall, the grey fulphuret yielding twenty per cent. of copper. It is de­scribed by Williams, that the metalliferous veins which enter this lode on the cafte fide and render it produc­tive, have never been found on the weft fide, fo that they appear to termi­nate in it. The rock near the great north and fouth vein is a soft killas or flate, but beyond this it is a very indurated flinty flate. This vein may properly be con­fidered as a crofs course, rendered rich in ore in various parts by a number of small veins which fall into it, like brooks into a large river where they are loft. The fitation of this mine is truly re­markable, at the foot of a precipitous cliff that overhangs the Atlantic ocean. If ever a fpot feemed to bid diftance to the ef­forts of the miner, it was this. At the very com­mencement of his labours, he was required to lower an im­mens steam-engine down a precipice of more than two hundred feet, with a view of extending his operations under the bed of the fea, where the workings are at prent con­tinued for feventy fathoms in length and fixty-five fathoms in depth. In thefe caverns of darknes, many human beings for a fmall pittance, and that even of an uncertain amount, are continually digging for ore, regardless of the horrors which surround them, and of the roar of the Atlantic ocean, whose boisterous waves are incessantly rolling over their heads. In some places the fea actually penetrates through; and it is worthy of obervation, that the water is deprived of a great portion of its salts; but whether this arises from fil­tration, or whether some portion of the fresh water from the land percolated through subterranean fissures in the rocks, we could not afermen when we vi{ited this fingular mine. If the filtration be more abundant after heavy rains, it would prove the intermixture of rain-water. The thin crofs courses filled with clay called flucean, heave the cafte and weft veins, and also hold up the water. The vein which is rich
in ore on one side of the flucan, will be poor on the other side. This fact, which we believe has not been sufficiently noticed, is well deserving attention, and would indicate that the presence of water affected the contents of veins.

Some veins contain little diversity in the nature of their contents, being filled principally with one kind of ore or vein-flone. Other veins contain a great variety of minerals, without any apparent regularity of arrangement: there are also numerous veins which have a regular structure, the different minerals being arranged in parallel layers, costing each other: the same succession of different minerals occur on each side and meet in the middle, filling up the vein, or sometimes leaving an empty space between. Thus calcaneous fpar, fluor fpar, barytic fpar, lead-ore, blende, and grey copper-ore, form different layers over each other in the same succession on each side of the vein. In the Botdock mine, before described, copper-ore is frequently found lining each side of the vein, and this is covered by tin; but in other parts of the mine the tin covers the walls, and is succeeded by copper.

*Irregular Veins.*—Befides rake-veins, which may be considered as regular, there are other veins which prehent a great variety of structure, and are called bellies, pipes, &c., according to their form. If a rake-vein be regarded as a tubular mass of mineral matter interfecting mountains; if this vein become irregular, and have its sides closed, or, as the miners call, twitched in, it forms what they denominate a pipe-vein, or mafs of ore and vein-flone sometimes of a tubular shape, de-\[-ing to a considerable distance like a pipe. In other infances, the sides are closed in both above and below, as well as on the sides, inclosing what the miners call a belly, or mafs of ore of considerable magnitude. Sometimes a small rib of ore is continued through that part of the rock where the sides of the vein are twitched in, until the vein expands again and produces another mafs of ore. In some infances there is no ore between, a rib of vein-flone or rider of clay being carried through the narrow part or twitch of the vein, but many of these twitches contain neither ore, clay, nor rider. In such cates, it becomes exceedingly difficult to follow the vein through the rock, to where it opens out again.

The veins in general do not close suddenly, but the sides gradually approach each other, and the ore terminates in the form of a wedge at the twitch.

These contractions or twitches are of various lengths, and no miner can tell, when the vein is so squeezed in, how many fathoms he must pass through before it opens again, unless the same twitch has before been cut through above or below the part where he is working. The intervening space between two mafs of ore is called a bar, and sometimes extends ten, twenty, or even a hundred fathoms or more; and when it is cut through, the ore makes its appearance, and begins gradually to widen and form another mafs or belly. When one of these bellies of ore proves pure and solid, it generally happens that all the contiguous bellies prove so in the same vein. According to Mr. Forfier, infances have been known of eight hundred hundred of ore being raised by fix miners from one of these bellies in the space of nine weeks.

When the matrix in these large bellies of ore is soft, the ore is generally found in a globular form, more or less irregularly imbedded in the flue materials, and these globular masses of ore are of various dimensions. It is no uncommon thing to find the soft openings in this kind of vein swell to an enormous width, so as to make it difficult to find the real sides of the vein. Working these veins is the most difficult part of mining, as there is no proceeding a foot without advancing timbers as far as they go, in the form of a passage in a houfe, compofed of two fide-polls, a lintel and a fell. The miners fand within this square frame, where they work and erec more timber as they proceed. It frequently happens that the ore is fo plentiful and rich in this kind of metallic repositary, as abundantly to compen-
and carbonate of lead, and has formerly been worked for the lead and copper, and more recently for the cobalt. Mr. Williams, in his "Natural History of the Mineral Kingdom," describes a singular stratum of flone near Lofouth, in the shire of Moray, of about eight feet thick, which is composed of several species of hard and fine flones of various beautiful colours. "This stratum is a kind of pudding-flone, in the composition which there is blended about an eighth part of good blue lead-ore or galena.

"This curious bed of flone is nearly horizontal, but dips away with an easy slope towards the north of the Moray Frith. The lead is found in larger and smaller grains and flowers, blended through the whole body and composition of the flone, in the same manner as the small mafles of agates and coloured cryfals, and other species of flone, are found blended through the whole body of the stratum."

Where metallic ore is thus intermixed with fragments of rock forming a conglomerate or breccia, it may probably be referred to the fame kind of metallic repository as fream-works, (see Strym-Works,) in which particles and mafles of ore are intermixed with fofe pebbles and fand, forming beds at the bottom of valleys, or on the sea-fhore, the metallic matter, as well as the pebbles, being derived from the diintegration of rocks containing metallic veins; but in the infance cited by Mr. Williams, the parts have become united, forming a folid stratum.

The manner in which metallic veins were filled with ore has greatly divided the opinions of geologists. George Agricola, a Saxon, who died in 1555, appears to have been the firft writer who had any diftinct knowledge of the structure of metallic veins, which he published in a work entitled "De Ré Metallica," and another work entitled "Bermanus." His theory of veins is in some refpects similar to that of Werner, which has lately excited much attention. According to Agricola, the rents or fiffures which are filled with metallic matter were partly formed at the fame time with the rocks themselves, and partly afterwards, by the waters penetrating the fover parts; fo that where there has been a larger quantity of water, or where the fubflance of the rock has been much softened, there the largest fiffures occur. With refpect to the earths and flones found in veins, he conceives the former to have been detached from the rocks and carried into the veins by water; the latter he considers as arising from the earthy matter, hardened partly by change of temperature and partly by a lapidifc juice. Minerals and metals he regards as being deposited from a folution in water, containing the earthy parts intimately mixed and combined with it in certain proportions. The folution of these mineral fubflances he conceives to have been greatly promoted by heat, on the abftrac of which they allumed their preffent folid form; the precious metals being the reful of a more pure and perfect folution.

Becher, in his "Phylica-Subterranea," published in 1669, afcribes the formation of metals and minerals to certain subterraneous vapours which arife from the bowels of the earth, and penetrating the fubflance of veins, produce a peculiar change in the earthly or ftony matter they meet with. He regards the earth as a hollow body, filled with clay, water, fufpufeous and bituminous fubflances, from which arife certain exhalations that form the metals. The celebrated German physician Stahl, confiders veins, as well as the fubflances they contain, to have been formed at the fame time with the earth itself, and of course as being contemporaneous with the rocks they interfet; but he is disposed to attribute some effeét to the action of air and other caufes.

Henkel, in his "Pyritologia," has given an ingenious theory of the formation of metallic veins, which has been adopted, with certain modifications, by fonie later geologists: he attributes the formation of ores to a peculiar exhalation produced and engendered by fermentation, supposéd by him to take place in the interior of rocks. The basis of each ore and mineral he supposés to exift in the fubflance of the rock, and by a peculiar procefs of nature it is matured and converted into the metal. He does not venture to afcertain the nature of these bafes, but in one passage he treats of subfte earths, in another of mercurial, arfénical, and fulphureous parts. These three last he probably confidered as conffuent parts, and the metals as com pounds. Air, water, and fire, are fubflances, according to this mineralogist, of which Nature avails herself in the formation of metals. He also supposés certain kinds of earths and ftones to exift, which ferve as the matrix for others, and which are indifpenfably neceffary in the formation of minerals.

Zimmerman, the pupil of Henkel, is the firft mineralogist who confiders veins to have been formed by a tranformation of the fubflance of the rock. Minerals, he fays, are undoubtedly formed in the rock; but daily experience fhes that the rock is not of itself capable of forming a metal, for were the mineralizing principle capable of converting it into a metal, we fhould find whole mountains which had undergone this change. But this change is only met with in certain directions, where the part of a rock, being thus transformed, contains veins. And he supposés that these vegetes or ftones, which have not suffered an entire change, or when they do not contain perfect metals, are fyll of a different nature from the rest of the rock. An attentive examination will fhew that they are of a decomposed and friable nature, appearing to have a tendency to return to this natural earthly flate, from which we may conclude that these veins were originally the fame as the rock, but that their texture had been altered and decomposed by fome particular saline fubflance, which penetrating the rents and fiffures, and had rendered them fit to be transformed into minerals.

Before noticing the theory of Von Oppel, which has since been adopted by Werner, we shall flate the opinions of thofe geologists who, with Henkel and Zimmerman, oppofe that veins have been filled by local caufes which may still continue to operate; whereas Von Oppel and Werner confider that they were formed by a general caufe, the operation of which ceased before the preffent flate of the globe. Lehman, in his treatife on the matrices of metals, published in 1755, fays, "the veins which we find in mines appear to be only the branches and fhoots of an infinite root which has been at a prodigious depth in the bowels of the earth, but in confequence of its great depth we have not been able to reach the trunk. The large veins are its principal branches, and the inferior ones the twigs. What I have faid," he adds, "will not appear incredible, when we confider that the bowels of the earth are, according to every obfervation, the workhoufe where Nature carries on the manufacture of the metals; that, from the beginning of the world, flie has been working at, and elaborating their primitive particles; that these particles infus forth, in the form of vapours and exhalations, to the surface of the globe through rents, in the fame manner as the fap fifies and circulates through vegetation by means of the vellels and fibres of which they are compofed."

The latter part of the theory of Lehman, which oppofes that changes are now taking place in the interior of the globe, by which metallic ores are flill forming, has been supported by many geologists, who have had opportunities of extensive obfervation. Mr. Von Trebra, sub-director of mines in Saxony, in his work entitled "Observations on the Interior of Mountains," advances a theory nearly fimilar to that of Zimmerman, and agreeing in part with Lehman.
VEIN.

From the third letter of that work we make the following extract.

"In explaining the phenomena which are observable in the interior of mountains (it must however be remembered, that I do not include such as are evidently of volcanic origin), I do not avail myself of those great causes which, by their magnitude, the fuldenners of their action, and by their effects, produce sudden changes which take place under our eyes, such as subterranean fires, earthquakes, and the like. I refer these phenomena to natural causes, which, though less evident and slower in their operation, are not less certain of producing a radical transformation. Of this kind are putrefaction and fermentation. It is of little consequence by what name we distinguish this peculiar action exerted by Nature in the mineral kingdom; it consists in an interstitial motion in the central parts of the globe, and appears to be produced by water combined with heat in different degrees of intensity. I observe such changes still going on, and can conceive them to continue so long as the same series of operations exist in nature. I am persuaded that there is constantly going on in our mountains a variety of transformations, compositions and decompositions, which not only take place at present, but will continue to the end of time.

"Fermentation, if I may be allowed to call by that name this quality which acts by insensible degrees, produces the most perfect transformations in the bowels of the earth; fermentation I say may, according to my theory, alter the entire mass of a mountain; it may convert granite into gneiss, as this last only differs from the former in its structure, which is flat or schistose; gneiss indeed has no other distinctive character than its structure, namely, the regularity and parallelism of its beds, and in some places a decomposed felspar approaching to clay. This fermentation may also convert greywacke into an argillaceous sluit, which last may again by induration become jasper, when this process is either diminished or stopped. By it, also, quartz may be converted into clay, calcareous intervals into quartz, and the whole mass of a mountain into inflammable or saline matter, or even into ores, metals, or fennemets. To it I ascribe the power of producing, preserving, and continuing to form the different beds and mineral repositories, which are found both in primitive and felsitz mountains: finally, the effects which the waters produce in filtering from above to below, and which in their passage through the different rocks may undergo some peculiar modification, appear to me the principal cause why this fermentation may act with more force in one part of the face of the mountain than in another."

Patriz, a celebrated French mineralogist, considers the changes taking place in the mineral kingdom, as effected by a processes somewhat similar to secretion in the animal and vegetable kingdoms, and ascribes a kind of mineral life to the earth itself, differing perhaps as much from vegetable life as the latter differs from that of animals. According to this theory, each kind of mineral subsistence is capable of converting malleable matter into its own peculiar nature, as animals convert their aliment into flesh and blood. Whatever may be thought of this theory, we believe that those who are most practically conversant with the various phenomena and transformations which occur in mines, will readily admit that many changes are taking place, which cannot be explained on any known chemical or mechanical principles, and which bear a strong resemblance in their effects to the processes of secretion. Nor can it, even in the present state of chemical science, appear improbable that the different earths and metals may be converted into each other by natural procetces. The different beds of rock intermixed by metallic veins are themselves metallic substances combined with oxygen; or, in other words, all the rocks and strata which form the earthy parts of the globe, confit of oxygen combined with metallic bases; and as these metallic bases may perhaps be compounded of the same elementary parts united in different proportions, the transmutation of one earth or metal into another, may be effected by a simple change in the arrangement of the elementary molecules.

The theory of veins propofed by Von Oppel, and in part supported and extended by Werner, supposes veins to have been fissures originally formed by the defecation of mountains, and the shrinking in of the mafis. These fissures, being open at the top, were afterwards filled with their contents by metallic solutions poured in from above. Mountains, according to Werner, have been formed by a successive accumulation of different beds and veins, piled one over another. "The subsidence of these beds was at first violent, and possessed little solidity; so that when the accumulation of matter had attained a certain height, the mafs of the mountain yielded to its weight, and mift consequtently have sunk and cracked. As the waters which inflit in supporting the mass began to retire, and lower their former level, these mafses then left their support, and yielded to the action of their weight, opening, and falling to the side where the least resistance was opposed. The shrinking of the mass of a mountain produced by defecation, and still more the fractures by earthquakes, and other similar causes, may also have contributed to the formation of fissures.

"The same precipitation, which in the humid way formed the strata and beds of rock, furnished and produced the subsidence of veins. This took place when the solution, from which the precipitation was formed, covered the existing rents, which were as yet wholly or partially empty, and open in the upper part. Veins, whether considered as rents, or as the substance constituting the vein, have been produced at very different times; and the antiquity or relative age of each can be easily determined."

"Such, in Werner's own words, are the great outlines of his theory, a theory which we conceive to be decidedly opposed by all the most striking appearances existing in the mineral kingdom, and equally opposed to the simplest known and acknowledged laws of nature. If metallic veins were once open fissures, filled by precipitations from a solution that covered the whole globe, with the highest mountains in which metallic veins are found; it is obvious that these metallic precipitations would be most considerable in the lower parts of the surface, in valleys and plains, where the fluid must have been much deeper than on the summits and sides of mountains. We ought, therefore, to find thick beds of metallic matter covering and involving the low and level parts of the globe; but nothing is more rare than to find beds of metallic matter in low places. Where beds of metallic matter exist, it is always in comparatively high countries, abounding in veins; and it is much more probable that the beds and veins were formed by local causes, and not from a solvent covering the whole globe. The metallic parts of this metallic ocean must have poiffued the greatest specific gravity, and instead of floating on the top of the fluid, to be deposited in the fissures at lofty mountains, it would have descended by the laws of gravity, forming cruts of different degrees of thickness from the bottom to the top, increasing downward. The reverse of this is the fact. It is principally in alpine difficulties, and at enormous heights, that metallic matter is accumulated in the greatest abundance. It is in the height of the Cordilleras of Peru that the productive veins of Potosi are situated: it is in the same chain of mountains, more or less
than 14,000 feet above the level of the sea, that the prodigious mass of mercurial ores is found at Guanac Velica, where, in the space of two centuries, more than 15,000 quintals of this metal have been procured.

But the facts most opposed to the theory of Werner are those which we have stated, namely, that when a metallic vein passes through different strata, the mineral suffilances it contains generally vary in each stratum, either in kind or quality. Sometimes an entire change takes place, as from tin to copper or lead; in other instances, the vein will contain the same kind of ore in the different strata, but it will be invariably richer or poorer in some of the strata than in others, and there will be certain strata in which scarcely any ore occurs. Very frequently where the same kind of metallic matter is contained in the vein, it will be mineralized or combined with different suffilances, as the vein passes through different beds; thus we find a metallic sulphuret more prevalent in one part, and a metallic salt or oxide in another part of the vein.

In Derbyshire, where the veins of lead pass through different beds of mountain lime-flone, which alternates with beds of bafalitic andyngloid, provisionally called toad-flone, it is found that the vein scarcely ever contains lead as it passes through the toad-flone, where it is always much narrower, and in some places appears to be entirely cut off by it; but on looking into the under beds of lime-flone, the vein is found again, and is as productive as in the upper beds. Where the vein can be traced through the toad-flone, it contains calcareous spar, and sometimes a few particles of lead-ore. If veins had been filled from above by metallic solutions, it is impossible to conceive that the nature of the rock could change the quality of the ore; much less could the ore disappear in one stratum, and appear again in a stratum below it. Professor Jamefon, in a paper published in the Memoirs of the Wernerian Society, has attempted to explain the difficulty presented by the interruption of the veins in Derbyshire, on the supposition that the different beds of lime-flone and toad-flone, together with the metallic veins, were contemporaneous, and that the toad-flone cut through the veins at the period of their formation. On this hypothesis, Mr. Bakewell, in his Introduction to Geology, remarks: "The existence of different organic remains in the upper and lower beds of the mountain lime-flone in Derbyshire, precludes the possibility of these beds having been all formed at the same time. The zoophytes in the lower beds of rock could not be living and co-existent with the shell-fish in the upper, nor with the vegetables, the remains of which are occasionally found in the sand-flone that covers the whole, and into which the veins sometimes shoot. Cuvier has well observed, that the existence of different organic remains in the upper and lower strata offers incontestable proofs that they were formed in succession over each other." In point of fact also, the veins are not always cut off by the toad-flone; but they are never productive of ore, where they pass through it, except in very small particles.

These facts are not less opposed to the igneous theory of metallic veins than to that of Werner. If metallic veins had been filled with their contents by the operation of subterranean fire, which cracked the surface, and injected the metallic matter in a flate of fusion, it is impossible to conceive that the nature of the rock, through which the veins pass, could have produced any material change in the quality of the ore. Metallic ores may, in some instances, have been formed slowly by exhalations from subterranean fires; as peculiar iron-ore, and even gold, has been found in the craters of volcanoes; and the phenomena, presented by the lava which destroyed Torre del Grecco in 1794, indicate the manner in which such ores are formed. The lava had buried entire houses for more than twelve months, at the latter end of which time it had considerably cooled; and when the houses were opened, pieces of iron were found converted into a flate of black, red, and magnetic oxyds, having the hollow parts and interfaces filled with a brownish-red transparent oxyd of iron, and with peculiar iron-ore. In the articles made of iron, which had undergone this change, the external form was scarcely altered, which evince that the crystals had been produced by sublimation. Copper articles were changed into crystralized red oxyd of copper, and red oxyd with green and blue carbonate. From the absence of metallic sulphurets, it is inferred that the lava contained little, if any, sulphur. These changes shew that metallic matter may be sublimed and converted into the flate of ore by subterranean heat, at a much lower degree of temperature than has been suppos'd.

There is a circumstance on which those who contend for the aqueous formation of metallic veins have laid much stress. In some instances, rounded pieces of flone, apparently resembling water-worn pebbles, have been found in mines at a considerable depth; but as many veins contain hollow spaces, through which water is continually running, the formation of pebbles might admit of a satisfac'tory explanation, without supposing that these pebbles had fallen in from above. The pebbles which we have seen of this kind, from the mines in Cornwall, are all of a chlorite fchilitus, and the form oblate, pre'enting the appearance which may be a frequent over lay of rocks of the same kind. It is in all probability an original formation, and not a breccia from pre-exil'ing rocks.

There is another circumstance which appears to have escaped the attention of geologists. The water in the mines of Cornwall, particularly in the vicinity of copper veins, has a temperature considerably above that of the natural temperature of the earth; it is said to be at 70° Fahrenheit; and the working miners, from its sensible warmth, can predi'd with certainty the vicinity of a copper vein. The increase of temperature, if any, in the vicinity of tin veins is lcss sensible.

From hence, as well as from various appearances in mines, we are led to infer that there are certain chemical changes now going on in the interior of the earth; and it is from a more enlarged acquaintance with these phenomena, that we can alone expect to obtain a satisfac'tory theory of the formation of metallic veins.

The following is a summary account of the rocks and situations in which metallic ores are generally found.

Platinum, and the recently discovered metals, palladium, rhodium, osmium, and iridium, have not been hitherto found in veins, but in the sands of rivers. The four latter metals are found as alloys in the grains of platinum. See PLATINA, PALLADIUM, &c.

Gold and silver are found in veins, and disseminated in primary and transition rocks, in porphyry, fentic, and the lower sand-flone. Gold has been occasionally discovered in coal, and is very abundantly disseminated in the sands of some rivers. See GOLD and SILVER.

Mercury is found in flate, in lime-flone, and in secondary flates. See MERCURY.

Copper occurs in veins and beds in primary and transition rocks, in porphyry and fentic, and occasionally in sand-flone. Mafies of native copper, of large fize, are found on the surface of the ground, in the interior of North America. See COPPER.

Lead and zinc occur in veins, and disseminated in primary and
VEIN.

Antimony occurs in veins in primary and transition mountains, except trap and serpentine. See Lead and Zinc.

Arsenic occurs in veins, either as a sulphuret or mineralizer of other metals, in primary and transition mountains, and in porphyry. See Arsenic.

Tellurium occurs in veins in porphyry, combined with gold. See Tellurium Mines.

Manganese occurs in beds and veins in primary and transition mountains, and in beds, and disseminated in red sandstone. See Manganese.

Molybdena, tungsten, and titanium, occur in granite, gneiss, mica-flake, and argillaceous schistus. These metals, with chromium and cerium, are very rare, and can only be reduced to the metallic state with great difficulty. See Molybdena, &c.

Mineral veins differ from metallic veins, being definite of ores, and filled with the same substances which compose entire rocks, or with earthy minerals.

Quartz veins (see Quartz) resemble in their structure and position many metallic veins; and it is not uncommon for a vein, which contains metallic ore in one part, to be intermixed with quartz and other vein-bones, will, in another part, be entirely filled with quartz. Quartz veins intersect almost all primary and transition rocks, but are particularly abundant in rocks of argillaceous schistus and greywacke. (See Rock.) The quartz in veins is most frequently white, and nearly opaque; and being much harder than the rocks which it intersects, it remains on the summits of mountains, after the surface of the rock is decomposed, until it is carried down by diluvial currents into the beds of rivers, where it becomes rounded by attrition, and is transported to distant districts. Most of the white quartz pebbles in England have probably been formed from the quartz veins of decomposed rocks, as no quartz of a similar kind exists as a rock in any part of England or Wales; but the same mineral abounds in veins.

Granite, argillaceous schist, slate, porphyry, greenstone, pitchstone, basalt, and various other rocks, frequently form veins in mountains of the same kind with themselves, or in different rocks. Where a vein of one kind of rock intersects a rock of a similar kind, the substance of the vein generally differs from that of the rock in texture, colour, and other characters. The granite in veins, which pass through granite rocks, will generally be coarser or finer grained than the rock which it passes through, and have the constituent parts differently mixed. The followers of Werner assert, that veins which contain rock substances have been filled from above by matter poured into the fissures, and that the granite in veins is of a secondary formation. They further maintain, that the lower rocks, which they consider as the older, never rise into the upper rocks in the form of veins. In opposition to this opinion, it has been discovered that veins of granite, in Cornwall, may be distinctly seen rising into the felsite or killas which covers the granite rocks in many parts of that county, particularly at St. Michael's mount, called of Penance, and at Mouffehole, two miles west of that town. Where the junction of the granite and felsite is exposed by the action of the sea, veins of the former rock may be traced, at low water, running in a zigzag form for many yards into felsite, gradually growing narrower, and terminating in small branches andtings. One circumstance we observed in the granite veins at Mouffehole, which may deserve notice: the same vein which penetrated the felsite, when it entered the granite, was different in texture from the granite rock, though it had the same constituent parts; it might be distinctly traced for a considerable distance into the granite. The granite also, in the vicinity of the felsite, was smaller grained than the general body of the rock; and the felsite, where in junction with the granite rock or granite veins, was changed to a kind of very fine-grained gneiss. These facts seem to indicate that both the granite and the felsite, to a considerable distance from their junction, had been in a softened state at the same time, and that their consolidation was contemporaneous. Similar appearances, with an intermixture of veins of felsite in granite, are present at Gisburn, and other parts of Scotland. Veins of granite, porphyry, or felsite, never penetrate the upper secondary strata; but veins of basalt and trap (see Trap) have been found in every kind of rock, even penetrating chalk. These veins are sometimes of vast extent and width, and frequently occasion great dislocations and derangements in the stratiifed rocks, particularly in the coal strata, where they have been most observed; hence they are called faults. (See Fault and Strata.) The dislocation of the strata by a vein of this kind is represented in Plate II. Geology, fig. 8, where the different strata, c, d, e, f, g, on the left-hand side, are separated from the corresponding strata on the right, and considerably elevated.

As the veins of trap or basalt are nearly vertical, and often several yards in width, and the substance with which they are filled being frequently harder than the strata which they intersect, these veins remain when the surface is decomposed to a considerable depth, rising like a wall or fence, which, in the language of North Britain, is synonymous with dyke; hence such veins have been called dykes, or robin-dykes, the term whin-dyke being used to denote basaltic rocks. (See Whin-stone.) Basaltic veins, or whin-dykes, vary in width from a few inches to several yards, and are sometimes more than one hundred yards wide. They often extend many miles in length; in other instances they terminate at shorter distances, forming irregular wedge-shaped mafles. When basaltic dykes are of considerable width, the basalt is interfaced by fissures; and sometimes the central parts and sometimes the fings are harder or looser than the other; and in some parts the basalt graduates into a dark ferruginous clay. Maltes of basalt from the dyke are frequently found wedged in between the strata, extending to some distance: and where basaltic dykes intersect coal strata, the coal in the immediate vicinity of the dyke has frequently the appearance of being charred. At Corshall-fell, in the county of Durham, the coal strata are cut through by a basaltic vein or whin-dyke, which is about sixteen yards wide. Where it comes in contact with the coal, the latter substance, for several feet, is converted into a pulvarenent flate, like wood. At a greater distance from the basalt, the coal is reduced to a coke or cinder, which burns without smoke, and with a clear durable heat. At the distance of fifty feet from the basalt, the coal is found in the flate of varicolored mineral coal. The roof over the coal is lined with bright red and black streaks of sulphur, probably fublimed by heat from the dyke; and the veines continue to coal. In these appearances we recognize every circumstance which might be expected from the agency of heat, but which would be extremely difficult to reconcile with the apparent formation of basalt. We have seen similar appearances near basaltic dykes in Northumberland. The vein, or dyke, of basalt
at Cockfied-fell, is part of the longest dyke which has been traced in England, or perhaps in any other country. According to the description of it in Mr. Bakewell's Introduction to Geology, "it extends from the western side of Durham in an eastward direction, to Bewick in Yorkshire, crossing the river Tees at this place, and proceeding in the same direction through the Cleveland hills, in the Eait Riding of Yorkshire, to the sea-coast between Scarborough and Whitby. It riles to the surface, and is quarried, in many parts of its course, for stone to repair the roads. It crosses the turnpike near the seven mile- stone from Whitby to Pukering, where there is a quarry sunk in it. The vein, or dyke, is here about ten yards wide; the stone is a dark greyish-brown basalt, and is the principal material for mending the roads in the district called Cleveland. The extent of this dyke has been traced in a direct line about seventy miles. In its course it interfets the metamorphic stone of Durham, the coal district, and the aluminous felsite. The circumstances attending this and other extensive dykes, which have not hitherto been regarded by geologists, completely invalidate," says Mr. Bakewell, "the theory, that these dykes were originally topogenous figures, formed by the shrinking or collapsing of the rocks. As the different rock formations through which it passes contain different organic remains, they must have been formed in succession at different periods, and the metamorphic stone, with the lower strata, must have been consolidated long before the upper strata were deposited; and the causes which might dispose the upper strata to shrink and open, cannot be supposed to act on the lower rocks. It is also remarkable, that the width of this vein is more than twenty yards in the lower rocks on the west; but in the upper rocks it is not more than ten yards. The dyke must have been filled with its contents at the time of its formation, otherwise it would contain fragments of the rocks which it interfets. As it passes through the limestone, it has rendered it more crystalline in its vicinity, and the effects in charring the coal, before deprived, point to subterranean fire as the original cause of its formation, and as the source whence the basalt that fills it was supplied. The close resemblance between the basalt and compact lava, add probability to the opinion that this great dyke was originally formed by an expansive force operating from below, which opened a chasm in the surface of the earth, and ejected the contents in a state of fusion. A volcanic dyke was formed on the western side of Velevius, June 12, 1794, two thousand three hundred and seventy-five feet in length, and two hundred and thirty-seven feet in breadth, through which lava rose to the surface. This lava, when cooled, formed a wall of stone interfeting the former beds of lava, and constituting a real dyke. The stone has a dark-grey colour, and is in some parts so compact as to resemble hornstone." See Volcano.

The effects of basaltic veins on the contiguous parts of the strata of sandstone which they interfet, are no lefs remarkable. In some inclusions, the sandstone appears very considerably indurated, and converted into a substance resembling hornstone.

It is observed by Mr. Allan, Tranactions of the Royal Society of Edinburgh, vol. vii. that the sandstone which is thus indurated, contains calcareous earth, which appears to have promoted its semi-vitrification; but where the sandstone remains unchanged in the vicinity of a dyke, the calcareous earth is wanting. Sir G. Mackenzie observed basaltic dykes in Iceland, the walls or sides of which were lined with a glossy substance resembling obsidian. These effects offer further illustration of the igneous origin of basaltic veins. A very interesting account of the effect produced by basaltic veins on the different beds of rock at the Giants' Causeway, and on other parts of the same range on the north coast of Antrim, is given in the third volume of the Transactions of the Geological Society.

Various beds of columnar basalt, argilliaceous lime-flone, and chalk, are interfeted by perpendicular dykes or veins of basalt. The chalk in the vicinity often undergoes a remarkable change, extending eight or ten feet from the wall on each side, and thence gradually decreases. The part nearest the basalt is converted into a dark-brown crystalline lime-flone, like coarse-grained primitive lime-flone. The next strata is that of fine-grained primitive lime-flone, or felscharne lime-flone; then fine-grained arenaceous lime-flone. A compact variety, having a porcelain aspect, and a blueish-grey colour, next succeeds; this, towards the outer edge, becomes gradually white, and indifferently graduates into unaltered chalk. The flints in the altered chalk assume a greyish-yellow colour. The altered chalk is highly phosphoricent when subjected to heat. In other parts of the range, the argilliaceous beds of flint appear converted into horn-flone by contact with the basalt, and consist in that strata the imbedded fossils peculiar to the flint strata. (See Strata.) The basalt in some of the veins is columnar; but the columns lie horizontally. It has been conjectured, with some probability, that this has been caused by its passing from a state of igneous fluidity, and the refrigeration commencing from the sides. From the same cause, in the beds of columnar basalt in that range, (see Giants' Causeway,) the columns are perpendicular, the cooling commencing from the top and the bottom of each bed. The marine organic remains in the strata over the basalt, prove that the whole were formed under the sea. In some instances, basaltic veins appear to have been opened, and the intervening space filled with debris from the upper strata; and there are basaltic dykes in Northumberland, in which the basalt being divided into irregular masses, the interstices are filled with iron-clay, and contain impressions of ferns, like those in the coal strata which these dykes or veins intersect. On the whole, no country in the world which has yet been examined presents so many interesting appearances of basaltic veins as the northern parts of Great Britain and Ireland, nor are they any where exposed to the eye of the observer with so much distinctness as on many parts of the sea-coast, where the ocean has bared the surface, and exposed the most magnificent and instructive sections of entire mountains, penetrated by these veins to the height of many hundred feet. The veins may often be seen extending from the mountains into the sea, rising up like enormous walls, which serve as monuments of the ravages of the ocean upon the coast. The great hardness of the substance which fills the veins has prevented their destruction by the waves that have broken down and removed the mountain masses in which these veins were once imbedded.

Messrs. Lewis and Clarke, the American travellers, describe extensive walls of dark columnar flone ranging through the interior of North America; these walls were undoubtedly dykes or veins of columnar basalt, remaining where the surface of the ground had been washed away. There are also inclusions where the substance of basaltic veins has been softer than the surrounding rock, and is washed out wherever the rock is exposed, forming deep fissures, with perpendicular walls of rocks on each side. Such appearances are not uncommon on the sea-coast in various parts of Scotland. For an account of basaltic rocks, see Trap.

Vein is also applied to the streaks, or waves, of divers colours appearing on several forts of stones, flones, &c.
VEL

as if they were really painted; and which the painters frequently imitate in painting wainscots, &c.

Marble is generally full of such veins.

Lapis lazuli has veins like gold. Ovid, speaking of the metamorphosis of men into flies, says—"Quix modo vena fut, tab codem nomine manit."

Veins, in flies, are often a defect, proceeding usually from an inequality in their constitution, as to hard and soft: which makes the stone crack, and shiver in those parts.

VEJOURS, or VIEWERS, Pifores, in Law, are perfons bent, by the court, to take a view of any place in quetion, for the better decision of the right.

It is also used for those who see such as effoim them-selves de mala bele, whether, in truth, they be such that they cannot appear, or whether they counterfeit.

VEIRAS, in Geography, a town of Portugal, in Alentejo; 15 miles N.E. of Estremos.

VEIRY, a town of France, in the department of the lake of Leman; 9 miles E. of Scieifel.

VEISSENBERG, a town of Russia, in the government of Revel, on the coast of the gulf of Finland; 56 miles E. of Revel. N. lat. 57° 22'. E. long. 26° 14'.

VEISENSHTEIN, a town of Russia, in the government of Revel; 32 miles S.E. of Revel.

VEIT, Str., a town of Germany, in the circle of Bavaria, and archchipsopie of Salzburg, near the Salza; 28 miles S. of Salzburg.—Alfo, a sea-port town of Ilftria, called aflo Fiume, situated near the gulf of Venice, on a narrow plain, which yields good grapes, figs, and other fruits. The harbour is formed by the Fiumara. For the convenience of exportation and importation, the emperor Charles VI. caused an highway to be made from this place to Carlhadt, in Croatia. A fugar-house has also been founded here. St. Veit is exempt from taxes and contributions; 3 miles S.E. of Triette. N. lat. 45° 46'. E. long. 14° 42'.—Alfo, a town of Germany, sometimes called St. Veit, in the duchy of Stiria; 3 miles S.E. of Pettau.—Alfo, a town of Germany, in the duchy of Carinhia, situated on the river Glun; 8 miles N. of Clagenfurt.—Alfo, a town of Germany, in the archduchy of Austria; 5 miles W. of Vienna.—Alfo, a town of Germany, in the archduchy of Austria; 11 miles W.S.W. of Freuhladt.

VEITA, a small island in the Mediterranean, near the east coast of Tunis. N. lat. 35° 1°. E. long. 11° 12'.

VEITH, Str. See St. Veith.

VEITSBERG, a town of Saxony, in the circle of Neufadt; 3 miles N.E. of Weyda.

VEITSHOCHHEIM, a town of the duchy of Wurzburg, on the Main; 20 miles S.W. of Schweinfurt.

VEL, in Ancient Geography, a town in the interior of Africa, and one of those which were subjugated by Cornelius Balbus. Pliny.

VELA, i: Geography, a rocky foord in the Spanish Main. N. lat. 15° 16'. W. long. 75°.

VEL, Cape de la, a cape on the N. coast of South America. N. lat. 11° 50'. W. long. 74° 46'.

VELABORI, in Ancient Geography, a people who inhabited the territory on the western coast of Hibernia, S. of the Ganges. Ptolemy.

VELACH, in Geography, a town of the duchy of Carinhia, at the union of the Campach and Moll; 11 miles N.N.W. of Saxenburg.

VELAGA, in Botany, Gaertn. v. 1. 245. t. 153; a name of Adamons's, adopted by Gartner, and belonging to the genus now called Pfaffospermum; see that article, under which it should be cited as a synonym.

VELAINE, in Geography, a town of France, in the department of the Meurte; 6 miles E.N.E. of Nancy.

VELAM, a town of Hindoofstan, in the country of the Nayrs; 34 miles E. of Calcutt.

VELAMEN, is used, by some Surgeons, for the bag, skin, or bladder, of an impohtume, or swelling.

VELAMENTUM BOMBYCINUM, a name which some anatomists give to the velvet membrane, or inner skin of the intestines.

VELANGODY, in Geography, a town of Hindoofstan, in Marwar; 7 miles W. of Tramman.

VELANI, in Botany and the Arts, sometimes called Valonia, a name given by the modern Greeks to the acorns of a species of oak, (see Quercus Agyios, and Quercus Inipotitaria,) denominated the "Velani." The tree grows on the western coast of Natoliz, in the islands of the Archipelago, in those of Corfu and Cephalonia, and throughout all Greece. For an account of the galls of this oak, we refer to the article GALLS. The Orientals take care to gather the galls at the precise time which experience has proved to be most favourable, or in which the excrecence has acquired its full size and weight. For this purpose, they visit the hills and mountains that are covered with oaks. The first galls that are picked up are laid apart; these are known in the East under the name of "Yeri," and distinguished in trade by the terms of "black galls" and "green galls." These which have escaped the first searches, and which are gathered a little later, called "white galls," are of a very inferior quality. The galls of the environs of Aleppo, Smyrna, Magnesia, Karihitar, Dargbekir, and the whole interior of Natoliz. The former are fold at Smyrna and at Aleppo two or three piaires less per quintal than the others. The inhabitants neglect to gather the acorns, which serve as food for the wild boars and goats; the latter contribute very much to render the oak small and stunted, by devouring, with its fruit, a part of its foliage and young boughs.

The diplopeps which produces these galls has a body of a fawn-colour, with the antenna dark, and the upper part of the abdomen of a shining brown. It is sometimes found, under its latter form, in the inside of the galls which are not yet pierced. On the same oak are found other galls in great numbers, which the inhabitants neglect to gather, because they are not fit for dyeing.

The velain, or valonia, is gathered in the autumn, and dried under the sun, which protect it from rain, and is in a proper state for shipping about the beginning of March; that which is gathered on the mountains is preferred to that of the valleys. There is also a difference with respect to its age or size; the small and young is taken from the trees before it has attained its full growth, and is much better than the large, or that which remains till it is full grown. Those of the best quality are usually sent to England, and the inferior to Ancona and Tralle. This gall is used for dyeing and tanning, and in Turkey a considerable quantity is consumed for the latter purpose.

The quantity shipped annually from the different Turkish ports may be calculated at from 2400 to 3200; it is sent to several places in Europe: particularly London, Liverpool, Leibnorn, Turfke, Ancona, and Greece. The oil, or kernel, of the valonia is not reckoned of any value, and is sometimes picked up on the figs and changes, [that is, freeing it from dirt, leaves, &c.] when it is from 12 to 15 for each, according to the quality of the article, and the
expence is from 30. to 40. per ton. The cup which
contains the nut or kernel constitutes the value of the valonia.
It has been used in this country many years by the dyers,
and has lately been introduced into the tanneries as a sub-
stitute for oak-bark, and the quantity used in this way has
been very considerable. The quantity imported into Lon-
don and Liverpool for the years 1811, 1812, 1813, amounted
to above 1200 tons per annum on an average. This was at
a time when oak-bark was scarce and dear; but when the
price of bark is low, the consumption of valonia is less ex-
tensive; for the leather manufactured with oak-bark is pre-
ferred to that prepared with valonia, chiefly on account of its
quality, as the colour of the leather is reckoned to be equal,
if not superior, to that which is tanned with bark. We
may here observe, that the great distance from which
valonia, or valani, is brought, and the heavy duty it pays,
compared with oak-bark, discourage its use; but if the
duty should be taken off, it is probable that the consump-
tion would be greatly increased.

VELANIDA, in Botany. See Quercus, n. 68.
VELARIUS, in Antiquity, an officer in the court of
the Roman emperors, being a kind of usher, whose post was
behind the curtain, velas, in the prince’s apartment; as that
of the chancellors, cancelli, was at the entry of the balfirade,
and that of the oficari at the door.

The velarii had a superior, of the same denomination, who
commanded them; as we find in two inscriptions, quoted by
Salmusius in his notes on Voplius, and by a third in Gruter.

VELASCO, DON ANTONIO PALOMINO, in Biography, was
a Spanish painter and historian of the artists of his country.
He was a native of Valencia, where he flourished about
1700. He was painter to Philip V., and painted many pictures
for the churches and convents of Valencia, Sala-
manca, and Grenada, but is much better known to us as an
author. He published an elaborate treatise on the art of
painting, in two folio volumes, in which he notices 350
painters and sculptors who had flourished in Spain previous
to the conclusion of the reign of Philip IV. Of this work,
there was an abridgment published in London in 1742,
etituled “Las Vidas de los Pintores y Statuarios eminentes
Espanoles,” of which there is an English translation.

VELASCO, in Geography, a town of North America, in
the province of Mexico.

VELASQUEZ DE SILVA, DON DIEGO, in Biography,
the most distinguished painter of the Spanish school, was
born at Seville in 1594. His parentage was noble, being of
a family originally of Portugal, which had established
itself in Andalusia. Though confined in fortune, they gave
him a liberal education, and, as he had evinced much inclination
for drawing, placed him with Francesco de Herrera,
the elder; but he afterwards became the disciple of F. Pa-
cheo, an artist of very considerable ability, and a scholar,
then residing at Seville. With him Velasquez studed atten-
tively, and his talents displayed themselves in a variety of
imitations of natural objects, particularly of peafantry in
their peculiar habits and occupations. Of these we have
now a specmen in England, which had at all times been
seen as a matter of exhibition of his early acquirements,
and celebrated under the appellation of the “Water Car-
rrier.” It was exhibited in the new palace at Madrid, but
was removed from thence by Joseph Bonaparte, and was
found, with a great number of other pictures, in the imperial
collection at the battle of Vittoria. It is now in the pos-
fession of the duke of Wellington, among the numerous other
trophies of that great man’s fame. Still, however, it is con-
idered by his grace as the property of the Spanish crown.
Velasquez continued attached to this particular application of
his art, conscious of his superiority, and declining to extend
his views to a more elevated class of subjects, till at length
the flight of some pictures by Guido and Caravaggio, which
Pacheo had received from Italy, excited his emulation, and
he then turned his thoughts to history and portraiture.
After he had been five years with Pacheo, that master be-
lowed upon him the hand of his daughter in marriage, and
he continued still to prosecute his art under the guidance of
that able instructor. In 1622, Velasquez left Seville, to
visit the metropolis of Spain and the Efeurial, and there
his talents recommended him to the notice of the count De
Oliveros, the favourite minifter of Philip IV., who pato-
nized and befriended him; taking him into his own palace
to dwell. Soon after he introduced him to the king, who
immediately ordered him to paint his portrait. From the
completion of this picture, which was upon a grand scale in
armour, and on horseback, the reputation of Velasquez was
established above all his contemporaries, and his patron was
ordered to inform him, that from that time the royal perfon
would be intrusted to no other painter but himfelf.

He received the royal permission to make a public exhibition of
it, when it was loudly applauded by all about the court, and
held up to public estimation by laudatory verfls in its
honour from the poets.

After this successful commencement of his public career,
he was employed to paint the portraits of the infants Don
Carlos and Don Fernando; and that of the minifter; his
patron, mounted, like his royal master, on a noble Andaluflan
charger, richly caparioned. He now, therefore, began to
enjoy the blessings of fortune, as well as thofe of fame.
He was appointed principal painter to the king, with a liberal
salary, besides receiving munificent remuneration for his
pictures, and being buly occupied in portraits.

He now also, in emulation of other Spanish painters, de-
termined to undertake a work upon a more extended scale
than he had before done, and took for his subject the ex-
pulsion of the Moors from Spain by Philip III. But, if
we may judge by the description given of the picture, it
does not appear to have polished much interefling matter
of a high historic quality; however, he gained great reputa-
tion from the skill with which he executed it. The com-
position represented the king armed, and in the act of com-
manding a party of soldiers, who are escorting a group of
Moors of different fexes and ages to the sea-shore for em-
barkation. On the other side is personified the kingdom of
Spain, as a majeftic matron, with a flately edifice. This
picture, as appears by an inscription upon it, was painted in
1627, and it was no sooner completed than he again ex-
perienced the munificence of his sovereign, who made him one
of his chamberlains, and allowed him an additional riper.

It was at this time that Rubens visited Madrid. He
formed an intimacy with Velasquez, and first inspired him
with a defire to visit Italy; and he obtained from his royal
patron every advantageous means of going there, with re-
commendatory letters to render his refidence in Rome
and Venice as useful and agreeable to him as poftible.

He embarked at Barcelona in 1629, and first landed at
Venice, where he was received and entertained by the Spa-
nish ambaffador. In this delightful birth-place of colouring,
the works of its great master Titian, in the palace of St. Mare,
excited his warm admiration, and he made several copies of
tem, and no one ever more thoroughly imbued the prin-
ciples upon which they are constructed. But perhaps it is
of Titoreto that Velasquez is more the imitator, than of
Titian. His freedom of pencil appears to have been more congelion with the tale of the Spanish, than the fober
and more correct hand of the former. After remaining at Ve-

nice a few months, he went to Rome, where he was molt graciously received by the cardinal Barberini, nephew to Urban VIII., who procured for him apartments in the Vatican, and access at all times to the works of Raffaello and M. Angelo. During his residence in Rome, he painted his celebrated history of Joseph's coat brought to Jacob; and also another very able work, of Apollo informing Vulcan of the infidelity of Venus; in which he had an opportunity of displaying his power of handling, and his admirable skill in colouring. Vulcan is at his forge, the light and shadow proceeding from which are most skilfully conducted: the strong and nucular forms of the Cyclops gracefully contrasted with the pure form of the Apollo; and the whole composition arranged with infinite judgment. Both these pictures were sent to Spain, and honoured by having distinguished places assigned to them in the palace of the king.

On his return home he went to Naples, and there painted the portrait of Donna Maria of Austria, queen of Ferdinand III. After about the lapse of a year and a half, he arrived at Madrid, and found his favour with his royal master undiminished. He was again lodged in the royal palace, and the king kept a key of his painting room, that he might have free access to him without ceremony; and this he frequently indulged himself with, as his great predecessor, Charles V., had done with Titian. And so strongly were the reminiscences in his powers, that it is said the king, going into his room one day, expressed some surprise, that a nobleman, to whom he had given a commission which required his absence from Madrid, had not departed, imagining that he saw him in the room, when it was in reality only his portrait.

In 1638, Velázquez painted his most celebrated picture of our Saviour on the Cross, for the conven of St. Placid, at Madrid; and about the same time, that of the general Pefcarra receiving the keys of a Flemish castle from the governor of the place. The management of all the different characters, the officers, &c. and the effect of the fortification, &c. of the town and landscape in the back-ground, is altogether eulogized by Mengs as the chef-d'œuvre of Velázquez.

Though his patron d'Olivarez fell into disgrace in 1643, yet Velázquez maintained his interest at the court; and in 1648, was commissioned by the king on a particular embassy to pope Innocent X., and at the same time was empowered to purchase for his majesty the finest works of art, both of sculpture and painting, which he could procure in Italy. On this occasion he embarked at Malaga, and having landed at Genoa, paffed through Milan and Padua to Venice, where he was well pleased to renew acquaintance with the great masters of art, whom he had before beheld with so much admiration. He afterwards visited Bologna; and on his arrival at Rome, was received with great favour and distinction by the pope; and in the unengaged moments of his more serious business, he painted a very fine portrait of his holiness, of which there is a capital exemplar at Luton, the seat of the marquis of Bute, which has every character of originality. For this painting, the pope gave him a gold medal and chain; and the academicians of St. Luke elected him of their body.

After a lapse of nearly three years, Velázquez took his departure from Genoa, in a vessel freighted with a magnificent collection of pictures, statues, busts, &c. which he had collected, and on his arrival was molt graciously received by the king, and honoured with further marks of his royal favour and bounty; among which the order of Santiago was not the least, as being confined to persons of the highest rank, or the most eminent abilities. He thus lived, in honour and riches, till 1660, when the ruthless hand of death put an end to his labours and enjoyments. He was buried with great funeral pomp in the church of San Juan.

VELATODURUM, or VELATODURUM, in Ancient Geography, a place on the route from Befançon to Epamondorum or Mandura.

VELAUNI, a people of the Maritime Alps near the fen, E. of the Nermiti.

VELAUR, in Geography, a river of Hindoosftan, which rises near Attore, in the Mytore country, and runs into the bay of Bengal, near Portonovo.

VELAY, before the revolution, a country of France, in Languedoc, situated to the W. of the Vivers, and the E. of Anvergne. It is mountaneous, but fertile: Le Puyen Velay was the capital. It now constitutes the department of the Upper Loire.

VELAZCGERD, a town of Pertia, in the province of Kerman; 54 miles N.E. of Gomron. N. lat. 28° 10'. E. long. 56° 34'.

VELBERG, a town of Germany, in the territory of the imperial town of Hall; 7 miles E. of Hall.

VELBERT, a town of the duchy of Berg; 5 miles N.N.E. of Medman.

VELBURC, a town of Bavaria, in the principality of Neuburg; 12 miles N. of Dietfurt. N. lat. 49° 10'. E. long. 12° 28'.

VELCERA, in Ancient Geography, a town on the coast of Illyria, between the mouth of the river Genaus and the town of Senia. Ptolemy.

VELDEN, in Geography, a town of Bavaria; 6 miles S.S.W. of Landshut.—Alto, a town of Germany, in the territory of Nuremburg, on the Pregnitz; 21 miles N.E. of Nuremburg. N. lat. 49° 37'. E. long. 14° 31'.

VELDENTZ, a town of France, in the department of the Sarre, formerly capital of a county, in the circle of the Upper Rhine, united with the palatinate; the environs are celebrated for an excellent Moselle wine: 17 miles E.N.E. of Treves. N. lat. 49° 53'. E. long. 6° 53'.

VELEA, a town of Hispania Citerior.—Alto, a town of Italy, S. of Placuita, in Gallia Cilipadana: now in ruins.

VELEN, in Geography, a town of Germany, in the bishopric of Munster; 22 miles W. of Munster.

VELETRI, a town of the Popedom, in the Campagna di Roma. This was a very ancient town, and considerable in the time of the first Roman kings. It was taken by Ancus Martius, fourth king of the Romans, and taken by the Vetulcians, under the command of Coreless. The Romans took it again some time after, and, removing the inhabitants, filled it with a Roman colony. It is the site of a bishop, united with Olbia, which is called the bishop of Olibia, but its residence is at Velence, 28 miles N.N.W. of Terracina. N. lat. 41° 42'. E. long. 12° 30'.

VELENZ, a town of South America, in New Granada; 100 miles from Santa Fe de Bogota. N. lat. 5° 52'. W. long. 75° 16'.

Velas de Guzman. See Guzmán.

Vellala Malaga, a seaport town of Spain, in the province of Granada, near the coast of the Mediterranean. The chief article of trade is raisins. In 1487, this town was taken from the Moors by Ferdinand, king of Catalonia and Aragon; 13 miles E. of Malaga. N. lat. 36° 47'. W. long. 4° 18'.

VELAS
VEL

VELLE, el Rubo, a town of Spain, in the province of Grenada, near the Guadalentin. This town was, in the time of the Moors, a strong place, and furnished with a garrison; 14 miles S. of Huesca.

VELEZAR, a river of Spain, formed by the union of the little rivers Bueria and Sil, on the confines of Leon, which, after receiving several other small streams, unites with the Minho, a little above Orense.

VELEZA, in Botany, was so named by Linnæus, at the recommendation of his pupil Læfling, in honour of Dr. Christofo Velez, examiner, first physician, and demonstrator of botany, at Madrid, who showed Læfling his manuscript Flora of the environs of that capital, which we do not find has ever been published.—Linna. Gen. 176.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, long and slender, with five angles, five intermediate furrows, and five pointed, erect, small teeth, permanent, without any appendages at the base. Cor. Petals five; claws linear, erect, very narrow, the length of the calyx; limbs spreading, oblong-wedge-shaped, cloven or toothed, hairy at the base, much shorter than the claws. Stam. Filaments ten, capillary, about the length of the calyx, inserted into the receptacle; anthers roundish, incumbent. Pist. Germin superior, cylindrical, short; styles two, thread-shaped, hardly 1 inch long as the flaments; filigines simple. Peric. Capsule cylindrical, slender, of one valve and one cell, opening with four teeth at the summit. Seeds numerous, oblong, alternate, imbricated downwards, concave in front, convex at the back, inserted in a fimple row, by the dorsal furrow, into a thread-shaped, unconnected receptacle. Eff. Ch. Calyx of one leaf, nearly cylindrical, furrowed, naked. Petals five, with very long claws; limb bearded at the base. Capsule superior, cylindrical, of one cell. Seeds imbricated.

A small genus of flandard campion-like plants, with numerous little pink flowers, nearly related to Saponaria, (see that article,) and certainly to be placed next to it in the artificial, as well as natural, systen. Linnæus knew but one species. We have a new one found by Dr. Sibthorp in Aifa Minor.

2. V. quadridentata. Four-toothed Velezia. Sm. Prodr. Fl. Grec. Sibith. n. 954. Fl. Grec. t. 391, unpubl.—Calyx club-shaped, smooth. Petals with four teeth. Gathered by Dr. Sibthorp in Aifa Minor, and, if we are not mistaken, in the isle of Patmos. This has the precise habit of the foregoing, but is rather larger, and quite smooth. The flowers are falked. Calyx angular, swelling upwards. Limb of the corolla marked like V. rigida, with a central flar; but each petal has four strong teeth, or acute lobes, instead of being only simply cloven. Each claw is crowned, in both species, with a tranverse row of white hairs. Stamens in the present all of equal length. Capsule rather ftrouter, shorter, and feds accurately cylindrical, than the former.

We have no doubt of this genus being equally distinct from Saponaria and Gypsophila, (see that articles,) though the fift species betrays aft moft affinity to the former, the fecond to the latter. An ovate, even calyx, and oblong capsula, are proper to Saponaria; a bell-shaped angular calyx, and almost globose capsule, to Gypsophila. Velezia is perhaps more naturally akin to Dianthus, but wants the fcales at the bottom of the calyx.

VELHAS, in Geography, a river of Brazil, which runs into the Parana.

VELIA, or Helia, in Ancient Geography, a town of Italy, in Lucania, westward, on a small gulf of the fame name, formed by the small stream Heles, from the Greek Helia, signifying a marph.—Alfo, a town of Hispamia Citror, belonging to the Caritii. Ptolem.

VELICALA, in Geography, a town of California, near the coast of the Pacific ocean. N. lat. 20° 35'. W. long. 115° 50'.

VELIDIA, a town of Morocco, on the coast of the Atlantic; 25 miles S.W. of Mazagan.

VELIKA, a town of Morlachia; 25 miles S.E. of Segna.—Alfo, a river of Croatia, which runs into the Save, near Craióva Velika.—Alfo, a river of Ruffia, which runs into the Vitack, 10 miles N.E. of Orlov, in the government of Vitacka.—Alfo, a river of Ruffia, which runs into the Tchudski lake, near Píkov.

VELIKIE LUKI, a town of Ruffia, in the government of Píkov, on the Lovat; 142 miles S.E. of Píkov. N. lat. 46° 28'. E. long. 30° 14'.

VELIKOI, a small illand of Ruffia, in the white sea. N. lat. 66° 45'. E. long. 32° 20'.

VELILLA, a town of Spain, in the province of Aragon. The author of the "Continuation of Mariana’s History of Spain," speaks of a bell in this town of great celebrity, which rung sometimes without the help of man; and that a particular description of its wonders was printed at Madrid in 1657.

VELINDO, a mountain of Naples, in Abruzzo Ultra; 12 miles S. of Aquila. This is one of the Apennines, and probably the highest of them. Its summit, 8397 feet above the Mediterranean, is covered with snow in June: about 46 geographical miles N.W. of Rome.—Alfo, a river of the Popedom, which runs into the Nera, about four miles from Terni, in the duchy of Spoleto.

VELINUS, (VELINO,) in Ancient Geography, a small river in the country of the Sabines, in the northern part; its sources were about twenty miles from Reate, towards the E., in mountains abounding with water. It paffed southward, by a place called Vacunis, afterwards by Intocrea, where it turned towards the W., to the plain on which was situated Cutileia. Changing its direction towards the N.W., it entered an immense plain, in which were high mountains, and formed a large lake. These
flagrant sulphuraceous waters were found very inconvenient. M. Curious pierced a mountain and made a canal to the Velinus, so that its waters had a free passage to the sea, by a valley, which Cicero compared to the valley of Tempé. The inhabitants of Reate found here abundance of roes, whence they called it Rosae. The Velinus discharged itself into the Nar near Interamna.—Alfo, one of the seven mountains of Rome.

V E L I C A S S E S, Velocasses of Caesar, Velocasses of Pliny, and Velocasses of Tolemy, were a people joined by Caesar to the Catall, and others among the Belgæ, separated by the Seine from the Celts. But in the division of Gaul by Augustus, the Velocasses, as well as the Catall, are placed in the Lyonnène, and they are referred to in that province by Tolemy and Pliny. Their capital, Rotomagus, became the metropolis of the second Lyonnène, when the Lyonnène of Augustus was divided into two provinces.

V E L I S C U M, a place of Africa, in Mauritania Cefa- rienfis, upon the route from Rufucurrum to Celama, between Sufafar and Taranumafa Caftra. Anton. Itin.

V E L I T E S, in the Roman Army, one of the four kinds of foot folders that composed a legion, who were armed lightly with swords, bows and arrows, flings, and javelins. For defensive armour they had only a small target, and a helmet or head-piece.

These were commonly young men of mean condition, and took their name a volaudo, or a velocitate, from their swiftness and expedition: and they were designated for skirmishing with the enemy before a battle, and pursuing them after a defeat.

They seem not to have been divided into any distinct bodies or companies, but to have hovered in loose order before the army.

The other classes of the Roman infantry were the haftati, principes, and triarii. In the day of battle, the haftati were placed in the first line, the principes in the second, and the triarii in the third. The Velites formed small flying parties both in front and rear. See Battle.

V E L I T I S, in the Natural History of the Ancients, the name of a peculiar sort of land used in the manufacture of glafs; for which purpose they always chose such as was found washed clean on the banks of rivers; and this they therefore called glas-fand, or velitis, or hyalitis.

V E L I T R Ė, or V E L I T R I, in Ancient Geography, a town of Italy, in Latium, in the country of the Volvisians. It was at some distance from the Appian way, S.E. of Alba, and became considerable under the Romans. It had an amphitheatre, of which no trace now remains. Two roads led to Velitra; one to the W. detached itself from the Appian way, the other to the E. communicated with the Latin way. See VELITRI.

V E L I Z, in Geography, a town of Russia, in the government of Polotsk; 88 miles E. of Polotsk. N. lat. 55° 20'. E. long. 31° 4'.

V E L L, in Rural Economy, a term applied in some districts to the bag or stomach of the calf, which is used in making running or runnet; or to the prepared stomachs of the animals or rennet for curdling the milk in cheesemaking, which are often called veils. In some dairies, instead of making the rennet ready some time previous to its being used, a small piece, proportioned to the quantity of milk to be coagulated, is cut from the vein the over-night, and put into half a pint of water, or whey, to infuse until the morning. In this case, the veils are to be fuppofed to be equal in goodness; and it is probable, that the virtue may not be fully extracted as by a longer infusion. It is fuppofed too as not improbable, that by the strength Vol. XXXVI. of the rennet might be a certain by means of experiment, by the application of alkali salts, and by such means be rendered more certain in its use. See Dairying.

Obf. V. Pfeudio-cyifus has the four larger filaments deftitute of anthers, and combined together in pairs. Linnae.

Ed. Ch. Pouch tymid, crowned with the leafy ovate style. Cotyledons folded. Calyx closed.

1. V. annua. Annual Crefe-rocket. Linn. Sp. Pl. 805. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 1444. N. affurwm fylvatere valentimum; Cluf. Hift. v. 2. 150. Bauh. Hift. v. 2. 920. Eruca nafurtio cognita tenuifolia; Ger. Em. 247, good.—Leaves pinnatifid. Pouches pen- dulous.—Native of fandy fields in England, Spain and Greece. With us it is a very rare plant, fearcely ever obferved but on Salisbury Plain, about Stonehenge, where it was first gathered by Mr. Iface Lawfon, in Ray's time, and has occasionally been feen fince, flowering in June. The root is fibrous, small and annual. Seed-leaves permanent for some time, inverfely heart-shaped, smooth. Herb variable as to luxuriance, erect; its stem about twelve or fifteen inches high, alternately branched, buffy, leafy, rough with defcended bristles. Leaves alternate, doubly pinnatifid, rough, with narrow blunt segments. Spike terminal, many-flowered. Calyx purplifh. Petals entire, sulphur-coloured, with purple veins. Pouch turned downwards as it ripens, about the fize of a hemp-feed, rough, crowned with the smooth, fpatulate, enlarged style, twice its own length. Seeds roundish, three or four in each cell.

—Native of the neighbourhood of Aranjuez in Spain, flowering in May. Sometimes kept for curiosity as a hardy greenhouse plant, but not remarkable for beauty. The stem is shrubby, branched, rough, two feet high. Leaves alternate, rather fefly, entire, rough, scarcely an inch long, tapering down into a short fuffath, and generally accompanied by two smaller leaves. Flowers in long spikes, yellow, with pale veins. Permanent style broad, nearly
VEL

VELLACHERY, a town of Hindoostan, in the Carnatic; 10 miles S.E. of Madura.

VELLADY, a town of Hindoostan, in Myfore; 14 miles S. of Dambottta.

VELLAS, a town of the island of Ceylon; 44 miles W.N.W. of Caudi. Lat. 5° 45'. E. long. 81° 16'.

VELLATOR, a town of Hindoostan, in Myfore; 5 miles E. of Coimbetore.

VELLECHYPALEM, a town of Hindoostan, in Myfore; 13 miles N. of Coimbetore.

VELLEIA, in Botany, received its name from the author of the present article, in honour of his highly valued friend, Col. Thomas Velley, F.L.S., author of a descriptive work on the Submarine Plants of Britain, with coloured plates, in folio, confessing of only one foliaceous. This amiable and accomplished botanist was unfortunately killed by accident, a few years since, in the town of Reading, as he was travelling between Bath and London.—Sm. Tr. of Linn. Soc. v. 4. 217. Brown Prodr. Nov. Holl. v. 1. 580. Labillard. Nov. Holl. v. 1. 54. (Euthales; Brown Prodr. Nov. Holl. v. 1. 579. Ait. Hort. Kew. v. 1. 363.)

Gen. Ch. Cal. Perianth inferior, unequal, either of three or five roundish leaves, or of one leaf in five segments, the upper division largest, permanent. Cor. of one petal, irregular; tube rather longer than the calyx, split longitudinally at the back, almost to the base, more or less tumid, or spurred, underneat; limb in five rather unequal, spreading, bordered, broad-keeled segments, almost two-lipped. Stam. Filaments five, thread-shaped, shorter than the tube, inserted into its membranous base, alternate with the segments of the limb; anthers erect, oblong, unconnected, of two cells, burfting lengthwise. Pijl. Germin superior, turbinate; style angular, rather longer than the flaments; stigma thick, obtuse, encompassed with a membranous, cup-shaped, abrupt integument. Peric. Capsule of one cell and four rigid valves. Seeds several, orbicular, compressed, roughish, imbricated on both sides of a central receptacle, shorter than the valves.

Eff. Ch. Calyx inferior, three or five-cleft, unequal. Corolla tubular, five-cleft, two-lipped; tube cloven at the back. Capsule of four valves and one cell. Seeds imbricated, orbicular, compressed.

Obs. Mr. Brown's Euthales is so strictly united in habit and character, except the calyx, with our Velleia, that we cannot but consider it as of the same natural genus. Our learned friend, from whom we always feruple to differ, has discovered some acknowledged Velleia with five leaves to the calyx, instead of three, originally attributed to it. Here then is an approach toward the five-cleft, though single-leaved, calyx of Euthales. Linnaeus has declared, Phil. Bot. sect. 170, 'Raro observatur genus in quo pars aliqua fructificationis non aberrat.' The calyx appears to be the part in Velleia which runs solid, if we may so translate it, and strikingly confirms the above maxim. We may extend this observation to the whole order of Mr. Brown's Goodenovia, in which even the situation of the calyx, whether superior or inferior, is not uniform; which circumstance must lead us to mistrust different theories in the same part, when not supported by other characters.

VEL

Without attention to such principles as these, we may almost, as Linnaeus says, make as many genera as species of plants.

Seçt. 1. Calyx of one leaf, in five segments. EUTHALES. Brown.

1. V. trierensis. Three-ribbed Velleia. Labill. Nov. Holl. v. 1. 54. t. 77. (Euthales trierensis; Brown Prodr. Nov. Holl. v. 1. 580. Goodenia tenella; Andr. Repof. t. 466. Curt. Mag. t. 1137.)—Calyx tubular, of one leaf, in five acute segments. Leaves downy.—Native of the south coast of New Holland. Sent to Kew Garden in 1803, by Mr. Peter Good. A perennial greenhouse herb, flowering most part of the year. The root is fibrous. Stem none. Leaves all radical, numerous, downy, more or less acute, tapering at the base; sometimes entire; sometimes toothed, or partly runcinate. Flower-flasks numerous, a span high, nearly erect, forked, with a pair of opposite lanceolate bracteas at each division. Flowers stalked, erect, yellow; keel of each segment green underneath; two upper ones marked in front with a dark brown spot; all emarginate; tube white, enclosing the filaments and style. The flowers seem variable in size. We should hardly, without Mr. Brown's authority, have supposed all the above synonyms to belong to the same species.

Seçt. 2. Calyx of five leaves. Corolla with a spur at the base, which is permanent. MENORESAS (a fiction of Velleia) Brown.

Seçt. 3. Calyx of three leaves. Corolla a little gibbous, on one side, at the base. TRUE VELLEIA. Brown.

4. V. lyrate. Lyrate Velleia. Br. n. 3.—Smooth. Bracteas distinct. Leaves lyrate, or sharply toothed at the base. Calyx-leaves roundish-ovate.—Native of Port Jackson, New South Wales. This is our original species of the genus. The leaves, all radical, much refulent those of Cryptis littorum. Stalk; a span high, rigid, once or twice forked; one branch at each fork being sometimes wanting. Bracteas ovato-lanceolate, acute, entire, separate at the base, with a small internal tuft of hairs. Flowers yellow, on short partial flasks. Calyx-leaves quite distinct, acute, nearly entire, a quarter of an inch long, downy within; the upper one rather broadest, and almost orbicular.

5. V. spatulata. Spatulate Velleia. Br. n. 4.—"Smooth. Bracteas distinct. Leaves spatulate, almost without teeth; quite entire at the base; with auxiliary tufts of hairs."—Observed by Mr. Brown near Port Jackson, as well as in the tropical part of New Holland.

7. V. perfoliata. Perfoliate Velleia. Br. n. 6.—"Smooth. Bracteas very large, combined, roundish, toothed."—Found by Mr. Alexander Gordon, in the neighbourhood of Port Jackson, but seen by Mr. Brown in a dried state only.

The whole genus is stemless, and we believe the flowers are all yellow. —None but the first species has hitherto made its appearance in the European gardens, though some of them might possibly prove hardy annuals, if not perennial with us.
VELLEIACIUM, in Ancient Geography, a town of Italy, in the midst of the hills of Gallia Cilipadana, according to Pliny.

VELLEITY, VELLEITAS, in the School Philosophy, is usually defined a languid, cold, and remits will.

Others say, it implies an impotency of obtaining what we require. Others will have it, a slight defire for something, which a person does not esteem much, or is too indolent to seek; as Catus amat pifcem, sed non vult tangerem lympbam.

VELLEIUS, in Biography. See Paterculus.

VELLEKAT, in Geography, rocks in the East Indian tea, about 15 miles E. from the island of Myol. S. lat. 2° 21'. E. long. 131° 2'.

VELLEPEKONDA, a town of Hindoostan, in Coimbatore; 15 miles S. of Varangole.

VELLIA, in Ornithology, a name used by some authors for the lanius minor, or lanius tertius of Aldrovand, called in England the falter.

VELLIAM, in Geography, a town of Hindoostan, in Coimbatore; 16 miles S.E. of Erroad.

VELLICA, in Ancient Geography, a town of Hispania, in the territory of the Tarrassone or Torely.

VELLICATION, among Physicians, the act of twitching or stimulating. The word is more particularly applied to a sort of sudden convulsions that happen to the fibres of the muscles.

VELLICULA. See Foricula.

VELLIN, in Geography, a town of Pomerania; 4 miles N.N.E. of Polnow.

VELLING, in Agriculture, a term applied to the operation or process of ploughing or cutting up and taking off the turf or upper surface of sward land, in order to its being burnt, or for other purposes. It is usually performed nearly in the same manner as baulking or wrel-baulking, except that instead of being turned over, the furrow-slice is, in some cases, cut with its turf upwards; and the work in this process is in effect the same thing; but as the outer point of the wing of the share in the plough is turned upwards, there is left necessity for holding it an oblique position.

The plough too in executing this operation, is always turned to the right upon the head-land, which is contrary to that which is practised in skirting, the slice or furrow being turned towards the ploughed instead of the unploughed land. In velling, the plough is thrown far into the land from the line of draught, as to enable the ploughman to carry with care about twice as much land as is displaced by the ploughed slice, which is pared very thin and even, and on the land side not cut so deep as in the operation of skirting, but gradually lifted and turned nearly on its green side upon the baulk, left on the right-hand or furrow side of the plough. This manner of ploughing, in contradistinction to splitting, is called, in some districts, gathering of the land; and the day-work five or six roods. See Splitting.

In cafes where the furrow-slice is not turned, it is in some places drawn out with small hooks, by the labour of women and boys, or hoarded, and then raked together in heaps, and burned. This is a mode of velling which is commonly adopted in cafes where there is not time to permit the turf or sod to rot, as is the case in other methods of practice. See Paring and Burning, and Turning to Rot.

VELLO, in Geography, a town of Italy, in the Veneto; 10 miles N. of Verona.

VELLON, in Commerce, a kind of money, in which accounts are kept in many parts of Spain. The real vellon is the most general money of account: it consists of 8½ quarts, 17 obolos, or 34 maravedis vellon. Madrid, and all Castile, with most of the adjacent provinces, and also Bilboa, Malaga, and Gallicia, keep accounts in reals and maravedis vellon. See MARAVEDI and REAL.

VELLOUL, in Geography, a town of Hindoostan, in Guzerat, on the coast; 9 miles W.N.W. of Puttan Sumnaut.

VELLUM. See VELOM.

VELLUM, in Geography, a town of Hindoostan, in the Carnatic; 5 miles S.W. of Tanjore. N. lat. 10° 43'; E. long. 70° 7'.

VELLY, Paul-Francis, in Biography, was born near Fives, in Champagne, in 1711. Quitting the society of Jefuits after having belonged to it for about eleven years, he devoted himself to historical researches. His chief work was his "Histoire de France," in 8 vols., written in an easy and correct style, and possessing the character of candour and truth. He is charged, however, with too often attacking the privileges of the clergy, and with having borrowed freely from Voltaire's Essay on General History, and with having been misled in some instances by adopting his sentiments. This history, which he terminated with Charles le Bel, was continued to the 16th volume by Villaret. He also published a translation of Swift's "Hilfory of John Bull." He was virtuous and amiable, and of a very cheerful disposition. His death happened in 1759.

VELMES, in Geography, a town of France, in the department of the Dordogne; 15 miles S.W. of Muclian.

VELOCE, Itali., in Music, swift; Velocimacro, superl. very swift.

VELOCITY, in Mechanics, quantity: that aection of motion, by which a moveable is disposed to run over a certain space in a certain time.

It is also called celerity, and is always proportional to the space moved.

Huygens, Leibnitz, Bernouilli, Wolthus, and the foreign mathematicians hold, that the momenta, or forces, of falling bodies, at the end of their falls, are as the squares of their velocities into the quantity of matter: the English mathematicians, on the contrary, maintain them to be as the velocities themselves into the quantity of matter. See Motion.

Velocity is conceived either as absolute or relative: the velocity we have hitherto considered is simple or absolute, with respect to a certain space moved in a certain time. Relative or respective velocity, is that with which two distant bodies approach each other, and come to meet in a longer or less time; whether only one of them moves towards the other at rest, or whether they both move: which may happen two ways, either by two bodies naturally approaching each other in the same right line, or by two bodies moving the same way in the same line, only the foremost flower than the other: for, by this means, this will overtake that; and as they come to meet in a greater or less time, the relative velocity will be greater or less. Thus, if two bodies come nearer each other by two feet in one second of time, their respective velocity is double that of two others, which only approach one foot in the same time.

Velocity is also uniform or equal, when a moving body passes through equal spaces in equal times; or unequal, when in equal times it passes through unequal spaces; in which case it is either accelerated or retarded; and this acceleration, or retardation, may also be equal or unequal. See Acceleration and Motion.
VELOCITY.

In the doctrine of fluxions, it is usual to consider the velocity with which magnitudes flow, or are generated. Thus the velocity with which a line flows, is the same as that of the point which is supposed to describe or generate the line. The velocity with which a surface flows, is the same as the velocity of a given right line, that, by moving parallel to itself, is supposed to generate a rectangle, always equal to the surface. The velocity with which a solid flows may be measured by the velocity of a given plane, that, by moving parallel to itself, is supposed to generate a cylinder, always equal to the solid. The velocity with which an angle flows, is measured by the velocity of a point, supposed to describe the arc of a given circle, which subtends the angle, and measures it. See Macl. Fluxions, book i. chap. 1.

All these velocities are measured at any term of the time of the motion, by the spaces which would be described in a given point of time, by these points, lines, or surfaces, with their motions continued uniformly from that term.

The velocity with which a quantity flows at any term of the time, while it is supposed to be generated, is called its fluxion. See Fluxion.

**VELOCITIES OF BODIES MOVING IN CURVES.** According to Galileo's system of the fall of heavy bodies, which is now abounded by all philosophers, the velocities of a body falling vertically are, each moment of its fall, as the roots of the heights from whence it has fallen; reckoning from the beginning of the fall. Hence that author inferred, that if a body fall along an inclined plane, the velocities it has, at different times, will be in the same ratio; for since its velocity is altogether owing to its fall, (and it only falls as much as there is perpendicular height in the inclined plane,) the velocity should be measured by that height as if it were vertical. See Inclined Plane.

The same principle, likewise, led him to conclude, that if a body fall through two contiguous inclined planes, making an angle between them, much like a fence when broken, the velocity would be regulated after the same manner, by the vertical height of the two planes taken together; for it is only this height that it falls; and from its fall it has all its velocity.

This conclusion was universally admitted till the year 1693, when M. Varignon demonstrated it to be false. From his demonstration it should seem to follow, that the velocities of a body falling along the cavity of a curve, for instance, of a cycloid, ought not to be as the roots of the heights, since a curve is only a series of an infinity of infinitely little contiguous planes, inclined towards one another; so that Galileo's proposition would seem to fail in this case too; and yet it holds good, only with some restriction.

All this mixture of truth and error, so near akin to each other, shewed that they had not got hold of the first principle; M. Varignon, therefore, undertook to clear what related to the velocities of falling bodies, and to set the whole matter in a new light. He still supposes Galileo's first system, that the velocities, at the different times of a vertical fall, are as the roots of the corresponding heights. The great principle he makes use of to attain his end, is that of compound motion.

If a body fall along two contiguous inclined planes, making an obtuse angle, or a kind of concavity between them; M. Varignon shews, from the composition of those motions, that the body, as it meets the second plane, loses somewhat of its velocity, and, of consequence, that it is not the same at the end of the fall, as it would be, had it fallen through the first plane prolonged; so that the proportion of the roots of the heights affected by Galileo does not here obtain.

The reason of this loss of velocity is, that the motion, which was parallel to the first plane, becomes oblique to the second, since they make an angle: this motion, which is oblique to the second plane, being conceived as compounded, that part perpendicular to the plane is lost, by the opposition thereof, and part of the velocity along with it; consequently, the less of the perpendicular there is in the oblique motion, or, which is the same thing, the less the two planes are from being one, i.e. the more obtuse the angle is, the less velocity does the body lose.

Now all the infinitely little, contiguous, inclined planes of which a curve consists, making infinitely obtuse angles among themselves; a body falling along the concavity of a curve, the loss of velocity it undergoes each instant is infinitely little; but a finite portion of any curve, how little soever, confining of an infinity of infinitely little planes, a body moving through it loses an infinite number of infinitely little parts of its velocity; and an infinity of infinitely little parts makes an infinity of a higher order, i.e. an infinity of infinitely little parts makes a finite magnitude, if they be of the first order or kind; and an infinitely little quantity of the first order, if they be of the second, and so in infinitum. Therefore, if the losses of velocity of a body, falling along a curve, be of the first order, they will amount to a finite quantity; in any finite part of the curve, &c.

The nature of every curve is abundantly determined by the ratio of the ordinates to the corresponding portions of the axis; and the essence of curves in general may be conceived as confining in this ratio, which is variable in a thousand ways. Now this same ratio will be, likewise, that of two simple velocities, by whose concurrence a body will describe any curve; and, of consequence, the essence of all curves, in the general, is the same thing as the concourse or combination of all the forces, which, taken two by two, may move the same body. Thus we have a most simple and general equation of all possible curves, and of all possible velocities.

By means of this equation, as soon as the two simple velocities of a body are known, the curve resulting from them is immediately determined. It is observable that, according to this equation, an uniform velocity, and a velocity that always varies according to the roots of the heights, produce a parabola, independent of the angle made by the two projectile forces that give the velocities; and, consequently, a cannon-ball, shot either horizontally or obliquely to the horizon, must always describe a parabola. The best mathematicians, hitherto, had laboured much to prove, that oblique projections formed parabolas as well as horizontal ones.

To have some measure of velocity, the space is to be divided into as many equal parts as the time is conceived to be divided into; for the quantity of space corresponding to that division of time, is the measure of the velocity. For an instance: suppose the moveable A passes through a space of 80 feet in 40 seconds of time: dividing 80 by 40, the quotient 2 shows the velocity of the moveable to be such, as that it passes over an interval of two feet in one second; the velocity, therefore, is rightly expressed by \( \frac{2}{2} \); that is, by 2. Suppose, again, another moveable B, which in 30 seconds of time travels 90 feet; the index of the celerity will be 3. Wherefore, since in each case the measure of the space is a foot, which is supposed every where of the same length, and the measure of time a second, which is conceived every where of the same duration, the
the indices of the velocities 2 and 3 are homogeneous, and therefore the velocity of A is to the velocity of B, as 2 to 3.

Hence, if the space be \( t \), and the time \( t \), the velocity may be expressed by \( \frac{e}{t} \); the space being in a ratio of the time and the velocity. See Motion.

**Velocity, Circular.** See Circular.

**Velocity, Initial, in Gunnery,** denotes the velocity with which military projectiles issue from the piece by which they are discharged. This is now known to be much more considerable than was formerly apprehended. For the method of estimating it, and the result of a variety of experiments by Mr. Robins, Dr. Hutton, &c. see Gun, Gunnery, Projectile, and Resistance.

We shall here add, that Mr. Thompson (Count Rumford) has lately published the result of a variety of experiments upon gunpowder, and also an account of a new method of determining the velocities of all kinds of military projectiles. From the equality of action and reaction, it appears, says Mr. Thompson, that the momentum of a gun must be precisely equal to the momentum of its charge; or that the weight of the gun, multiplied into the velocity of its recoil, is just equal to the weight of the bullet and of the powder (or the elastic fluid that is generated from it) multiplied into their respective velocities: for every particle of matter, whether solid or fluid, that issues out of the mouth of a piece, must be impelled by the action of some power, which power must react with equal force against the bottom of the bore.

It is easy to determine the velocity of the recoil in any given case, by suspending the gun in a horizontal position by two pendulous rods, and measuring the arc of its ascent by means of a ribbon, according to the method which Mr. Thompson has described, and this will give the momentum of the gun, its weight being known, and consequently the momentum of its charge.

But in order to determine the velocity of the bullet from the recoil, it will be necessary to find how much the weight and velocity of the elastic fluid contribute to it. That part of the recoil which arises from the expansion of this fluid is always very nearly the same, whether the powder is fired alone, or whether the charge is made to impel one or more bullets, as Mr. Thompson has determined by various experiments.

If, therefore, a gun, suspended according to the method proposed, is fired with any given charge of powder, but without any bullet or wad, and the recoil is observed; and if the same piece is afterwards fired with the same quantity of powder, and a bullet of a known weight, the excess of the velocity in the latter case above that in the former, will be proportional to the velocity of the bullet; for the difference of these velocities, multiplied into the weight of the gun, will be equal to the weight of the bullet multiplied into its velocity.

Accordingly, if \( W \) is put for the weight of the gun; \( U \), for the velocity of its recoil, when it is fired with any given charge of powder, without any bullet; \( V \), for the velocity of the recoil when the same charge is made to impel a bullet; \( B \), for the weight of the bullet; and \( w \) for its velocity; we shall have \( v = \frac{V - U \times W}{B} \). Let \( B = 580 \) grains, \( W = 336,000 \) grains; and, therefore, \( B : W :: 580 : 336,000 \);

\[ i.e. : 1 = 579,31 \text{ nearly, and } V - U \text{ is found by experiment to be equal to } 1.8522; \text{ and, consequently, } v = 1.8522 \times 579.31 = 1073 \text{ feet in a second; which is very near } 108 \text{ feet in a second, the mean of the velocities determined by the pendulum after the manner of Mr. Robins.}

But the theorem will be rendered more simple by putting \( c \) for the chord of the recoil in English inches, when the piece is fired with powder only, and \( C \) for the chord when a bullet is discharged by the same charge; and then

\[ C - c \text{ will be as } V - U; \text{ and consequently, as } \frac{V - U \times W}{B} \]

which measures the velocity of the bullet, the ratio of \( W \) to \( B \) remaining the same.

Supposing, therefore, \( C - c = 1 \) inch, and the velocity of the bullet to be computed from that chord; the velocity in any other case, in which \( C - c \) is greater or less than one inch, will be found by multiplying the difference of the chords \( C \) and \( c \) by the velocity that answers to a difference of one inch. Or the velocity of the bullet, expressed in feet per second, may in all cases be found by multiplying the difference of the chords \( C \) and \( c \) by 118.35; the weight of the barrel, the length of the suspending rods, and the weight of the bullet, remaining the same, whatever be the charge of powder or its strength.

According to this rule, Mr. Thompson has computed by several experiments the velocities of bullets from the recoil, and compared them with the velocities obtained by the pendulum. The result, making the necessary allowances for the difference in the conclusions arising from these two methods, leads Mr. Thompson to infer, that there is the greatest probability that the velocities of bullets may in all cases be determined by the recoil with great accuracy; and if this method succeeds with musquet-bullets, it may also be applied as well to cannon-balls and bomb-shells of the large dimensions: he apprehends also, that it will be much preferable to any other method hitherto known, not only as it may be applied indifferently to all kinds of military projectiles, with little trouble or expense, but also because by this method the velocities with which bullets are actually projected are determined; whereas, by the pendulum, their velocities can only be ascertained at some distance from the gun, after they have lost a part of their initial velocities by the resistance of the air through which they are obliged to pass to arrive at the pendulum.

Those who advert to what has been delivered under the article Gunnery, will find that, according to Mr. Robins's theory, farther confirmed by Dr. Hutton's experiments, when bullets of the same diameter, but different weights, are discharged from the same piece by the same quantity of powder, their velocities should be in the sub-duplicate ratio of their weights.

But this theory, says Mr. Thompson, is founded upon a supposition, that the action of the elastic fluid, generated from the gunpowder, is always the same in every given part of the bore when the charge is the same, whatever may be the weight of the bullet; and as no allowance is made for the expenditure of force required to put the fluid itself in motion, or for the loss of it by the vent, he concludes that the theory is defective. And from a variety of experiments, made with a view of ascertaining this point, he infers, that the ratio of the velocities of bullets to their weights is different from that which Mr. Robins's theory supposes; and from other experiments he finds, that the velocities computed, according to the reciprocal sub-duplicate ratio of the weights, agree much better with the result of experi-
duced from those experiments, than those computed upon
Mr. Robins's principles; though, in this mode of com-
putation, the difference between the actual and computed vel-
cocities was in some of the experiments inconsiderable. But
as the powder itself is heavy, it may be considered as a
weight put in motion along with the bullet; and if the
density of the generated fluid be supposed always uniform
from the bullet to the breech, the velocity of the centre
of gravity of the powder, or of the elastic fluid, and the gros
matter generated from it, will be just half as great as the
velocity of the bullet; putting, therefore, $P$ to denote the
weight of the powder, $B$ the weight of the bullet, and $v$
it initial velocity; then $B v + \frac{1}{2} P v = B + \frac{1}{2} P \times v$
will express the momentum of the charge at the instant when
the bullet quits the bore. Instead, therefore, of acertaining
the relation of the velocities to the weights of the bullets,
he proposes to add half the weight of the powder to the
weight of the bullet, and to compute the velocities from
the reciprocal sub-triplicate ratio of the quantity $B + \frac{1}{2} P$:
and the result of several experiments shows an agreement
between the actual and computed velocities that is very
remarkable.

We shall only add, that Mr. Thompson disputes the juj-
ness of Mr. Robins's conclusion with respect to the force
of gunpowder, which makes it 1000 times greater than the
mean preflure of the atmosphere; whereas, from the refult
of one of his experiments, its force appears to be at least
1508 times greater than the mean preflure of the atmosphere.
Phil. Trans. vol. lxxi. part ii. p. 329—332.

Sound, Wind, &c.

**VELOM, or VELLUM, is a kind of parchment (which
see), that is finer, evener, and more white than the common
parchment.

The word is formed from the French velin, of the Latin
vitulinus, belonging to a calf. See Artorive.

For regulations relating to makers of vellum, and duty
on the same, see Leather.

**VELORE, in Geography, a town of Hindooflan, in the
Carnatic; 14 miles W. of Arcot. N. lat. 12° 54'. E.
long. 79° 15'.

**VELOSO, a town of Portugal, in the province of
Bora; 14 miles S. of St. Joao da Pesqueira.

**VELPE, a river of Brabant, which joins the Dener,
at Halen.

**VELPI, in Ancient Geography, mountains of the Cy-
renaica, on the confines of Africa Propria. These mount
ains were inhabited by the Macatuce, according to Ptol.
my.

**VELSER, or WELSER, Mark, in Biography, was born
at Augsburg, of an ancient and opulent family, in 1558,
and educated at Rome under the celebrated Muret. Upon
his return to his native city he practifed at the bar, and be
came a feator in 1592, and having attained the highest rank
in the government of the city, he was regarded as its chief
ornament; nor was he left difguifed as the promoter of
literature and science. He died in 1614, at the age of 56.
The principal of his works, which are numerous, are "Re-
rum Auguitanae Vindelicarum Libr. VIII." Venet. 1594,
and "Rerum Boicarum Libri V." Aug. Vind. 1602. He
was a principal contributor to Gruter's Collection of In-
scriptions, and he aided many others in their publications.
A collection of his writings was published in a folio volume

**VELT, or VELTE, in Commerce, a measure for brandy
in several parts of France. At Bourdeaux, brandy is con-
tained in caills of 50 vels, more or lefs; but it is fold by
the barrique of 32 vels, or about 60 English gallons: 5
velts proof of Bourdeaux make 4 velts proof, by which it
is fold in London. At Cognac, it is fold by the 27 velts;
and 11 velts proof of Cognac make 10 velts proof, by which
it is fold in London. At Rochelle, brandy from this place,
Cognac, Isle de Rhe, and the river Charente, is in caills of
3 barriques, containing in all 75 or 90 velts, and is fold
by the 27 velts: 16 velts = about 31 English gallons. At
Bourdeaux, 1.64 barrique = 100 English gallons, and each
barrique measures 14.033 cubic inches: 52.74 velts = 100
English gallons, and each velt = 438 cubic inches. At
Cognac, 51.68 velts = 100 English gallons, and each velt
measures 447 cubic inches. At Nautes, 67.34 velts = 100
English gallons, and each velt measures 343 cubic inches.

**VELTE, in Ancient Geography, a people of European
Sarmatia, in a part of the Venedic gulf.

**VELTHAUSEN, in Geography, a town of Ger-
many, in the county of Bentheim; 2 miles N.N.E. of
Nienhuis.

**VELTHEMIA, in Botany, received its name from
professor Gleditsch, in the Berlin Transfections for 1769,
in compliment to a German nobleman, Augustus Ferdinand
von Veltheim, author of several mineralogical works, and
reported to have been also a lover and patron of botany.—
Poiriet in Lam. Dict. v. 8. 448.—Clafs and order, Hexa-
Jaff.

Gen. Ch. Cal. none. Cor. of one petal, tubular, nearly
cylindrical; limb regular, in fix very short, broad, almoft
equal, segments. Stam. Filaments fix, thread-faded, in-
tered into the tube and not projecting beyond it; anthers
ovate, cloven at the base. Pfl. German superior, roundifh;
style thread-faded, declining; stigma simple, acute. Perti.
Capfule membranous, somewhat pellucid, three-lobed, three-
seelled, each lobe extended into a compreffed rounded wing.
Seed mostly follicular, obovate, rather compreffed.

Eff. Ch. Corollis tubular, with fix teeth. Stamens in-
tered into the tube. Capfule membranous, with three
wings, and three cells, with follicular fees.

Ofb. This genus, confounded by Linnaeus with his
Aletris, is well separafed therefrom, as well as from Tri-
toma, (fee thofe articles,) both on account of their habits
and characters. The genuine Aletris has a funnel-faded
corollaf, into the bafe of whose segments the
flaments are inferted; and many feeds in each cell of the cap-
fule. Trifoma is diftinguifhed by its long flaments, inferted
into the recepftacle, and projecting far out of the flower.

Ait. n. 1. Jacq. Hort. Schoenbr. v. 1. 41. t. 78. (V. ca-
penis; Redout. Liliac. t. 193. Aletris capenis; Linn.
Sp. Pl. 456. Curt. Mag. t. 501. )—Leaves lanceolate, ob-
tufe, with wavy plates. Teeth of the corolla rounded, eret.

—Native of the Cape of Good Hope, from whence its
bulbs are faid to have been first imported into this country
in 1768, by the late Mr. Malcolm. The plant is now frent
in molt good greenhoufes, flowering copiously in the winter
and spring, yet it is not evenly increafed, either by root or
by fee. The bulb is ovate, larger than a hen's egg.

Leaves numerous, all radical, spreading, smooth, a fpan
long,
long, entire, broadly undulated; of a deep grays-green above; pale and glaucous beneath. Stalk solitary, erect, straight, naked, eighteen or twenty inches high, elegantly spotted and streaked with blood-red or purple, bearing a long, dense, ovate _chryfis_, of pendulous inodorous _flowers_, each accompanied by an awl-shaped pink _bractea_, much longer than its _flalk_. The _corolla_ is of a waxy pink, or glaucous rose-colour, pale yellow, or greenish, without the extremity; its length about an inch and a half. _Capsules_ nearly the same length, of a tender bladdery texture, pale and pellucid, so as to shew the black _seeds_ within.

2. V. _glauca_. Glaucous-leaved Veltheimia. Willd. n. 2. Alt. & n. 3. Curt. Mag. t. 1991. Jacq. Hort. Schoenbr. v. t. 40. t. 77. ( _Aletris glauca_; Alt. ed. 1. v. t. 463.) Leaves lanceolate, glaucous, tipped with a small point; somewhat crisped at the margin. Teeth of the corolla spreading.—Native likewise of the Cape of Good Hope, from whence it was brought to Kew garden by George Wyngh, ed. in 1781, being among the many new species of plants, chiefly from that country or from America, for the knowledge of which the botanical world is indebted to the late Mr. Aiton, and his learned coadjutors, in the first edition of the _Hortus Kewensis_. The number of _Vellum_ is greatly increased in the second edition, principally from New Holland and the East Indies. No work of the kind has furnished so many. The plant before us differs from the preceding in having a more oblong pointed _bulb_; much straighter and more erect _leaves_, glaucous on both sides, whole marginal undulations are flight and very small. The _flowers_ are smaller, paler, and less _showy_; their marginal _stigma_ more expanded. This is much more rare than _V. viridifolia_, being more difficult of culture and less handsome. It flowers from January to April. For the two other species referred to this genus by Willdenow, _Uvaria_ and _pumila_, see _Tritoma_.

VELTZEN, or _Ulzen_, in _Geography_, a town of Westphalia, in the principality of Luneburg; 20 miles E. of Luecko.

VELVALEG, a town of Grand Bucharia; 5 miles S. of Archenk.

VELUCA, in _Ancient Geography_, a town of Hifpania Citerior, belonging to the Arevaci. Torey. _Velvet_, a rich kind of stuff, all _ilk_, covered on the outside with a _clofe_, short, fine, _soft flage_, the other side being very strong and close.

The word is formed of the French _velours_, which signifies the _name_, and which comes from _velis_, a thing covered with hair. The _knop_ or _flage_, called also _velowing_, of this stuff, is formed of part of the threads of the warp, which the _workman_ puts on a long narrow _channelled ruler_, or _needle_, or _wire_; and which he afterwards cuts, by drawing a sharp _steel tool_ along the channel of the needle to the ends of the warp.

The principal and best manufactories of _velvet_ are in France and Italy, particularly at Venice, Milan, Florence, Genoa, and _Lucca_; there are others in Holland, set up by the French refugees, of which that at _Haerlem_ is the most considerable.

Velvets are now made to great perfection at Manchester and other parts of England. There are some brought from China, but they are the worst of all.

There are velvets of various kinds, as plain, that is, uniform and smooth, without either figures or stripes:—figured, that is, adorned and worked with divers figures, through the ground be the same with the figures; that is, the whole surface velveted:—_ramages_, or _branched_, representing long stalks, branches, &c. on a satin ground, which is sometimes of the same colour with the velvet, but more usually of a different one. Sometimes, instead of _fattin_, they make the ground of gold and silver, whence the denominations of _velvet with gold grounds_, &c.:—_unet_, that in which the threads that make the velveted, have been ranged over the channelled ruler, or wire, but not cut there:—_striped_, that in which there are stripes of divers colours running along the warp; whether those stripes be partly velvet and partly _fattin_, or all _velvet_;—_cut_, that in which the ground is a kind of _taffety_, or gros de Tours, and the figures velvet.

Velvets are likewise distinguished with regard to their different degrees of strength and goodness, into velvet of four threads, three threads, two threads, and a thread and a half: the first are those where there are eight threads of _flag_, or _velvetings_, to each tooth of the reed; the second have only six, and the rest four.

In general, all velvets, both worked and cut, _thorn_ and flowered, are to have their warp and _flage_ of _organzine_, spun and twilled, or thrown in the mill, and their _woof_ well boiled, &c. They are all of the same _breadth_.

VELUM, in _Ecclesiastical Writers_, the name with what is otherwise called _branдумал._

VELUM _Quadrageminate_, a veil or piece of hangings, anciently drawn before the altar in Lent, as a token of mourning and forrow.

VELUM, in _Anatomy_, a part in the brain. See _Brain._

VELUM _Pallatii_, or _Pendulum_, the soft palate. See _Deglutition._

VEMANIA, called _Viana_ by Ptolemy, in _Ancient Geography_, a place of Rhetia, upon the route from Pannonia in the _Gauls_, in passing by _Sopiance_, between Cambodunum and Brigantia. In. Anton.

VEMMETSTOSTE, or WEMMELSTOSTE, in _Geography_, a town of _Bucharia_, in the _coast_ of the island of Zealand; 6 miles S.W. of _Heding_.

VEMPSUM, in _Ancient Geography_, a town of Italy, in Latium. _Ptolemy_.

VEN, in _Geography_, a town of _Naples_, in _Calabria_; 9 miles N.E. of _Squillace_.

VEN, in _Mythology_. See _VINO_.

VEN, _Vein_, in _Anatomy_. See _VEIN_.

VENABULUM, in _Antiquity_, a long kind of _speur_, used in hunting wild beasts.

VENE LACITER, in _Anatomy_, the absorbing vessels, so called because they were suppos'd to be veins. See _Lacra Vaia._

VEN._ _LYMPHATICA_. See _Lymphatics._

VENAFRO, in _Geography_, a town of _Naples_, in _Lavora_, the see of a bishop, _infrigran_ of _Capua_; 14 miles N. of _Sezza_. N. lat. 41° 30'. E. long. 15° 58'.

VENAFEUF, ( _Venafro_ ), in _Ancient Geography_, a town of Italy, in _Campagna_, northwards, towards the _Samnium_, which became a Roman colony. It was famous for its olives and oils.

VENAISSIN. _Count of_, _County of_, _Venaissin_, in Geography, a country of France, bounded on the N. by the department of the _Drôme_, on the E. by the department of the Lower Alps, on the S. by the department of the _Mouths of the Rhône_, and on the W. by the _Rhône_, which separates it from the department of the Gard, about 12 leagues in length, and 5 in breadth. It takes its name from _Venaissin_, the _Vendange_ or _Vendasea_ of the _seigneurs_, and was polled, after the 11th century, by the counts of _Tomblay_.

VENS VEN. VEN. VENS._ _LYMPHATICA_. See _Lymphatics._
VENAL, or VENOUS, among Anatomists, something that bears relation to a vein.

The extremities of the cava and pulmonary veins, where they enter the auricles of the heart, are called venous sinu. See Venes. - VENAL. - VENAL, formed from venalis, to be sold, is also used for something bought with money, or procured by bribes.

Thus we say, venal bands; court ezans and flatterers are venal; even justice, in Turkey, is venal, and must be bought of the baflaws.

In England, there are several offices in the revenue, policy, &c. venal; but this vanity of offices is no where so considerable as they were in France, where all offices of judicature were bought of the king, and only municipal officers are elected. Offices in England are venal only by a kind of connivance; in France it was a thing solemn and authorized. The vanity was first introduced by Louis XII., who, to clear those immense debts contracted by his predecessor Charles VIII., without burdening his people with new taxes, bethought himself to sell the offices of finance; and, in reality, he made a vall fum by it; but he forbad, by an edict in 1568, the sale of offices of judicature. Francis I. made an advantage of the same expedient to get money, and fold his pofts, not excepting the offices of judicature, openly: under this king, it was only accounted a kind of loan; but that loan was no more than a name to dignifie a real fale. However, it is faid, that the sale of offices of judicature was established by edicts of Charles IX. and that military offices were fold under the reign of Henry III.

The parliament, not being able to rehali the vanity of offices, always made the buyer take an oath that he did not buy his poft, either direcdy or indirectly; but there was a tacit exception, made of monies lent the king for being put into them. At length the parliament, finding its oppositions were in vain, and that the trafficking of offices was publicly authorized, abolished the oath in 1597.

VENAMALI, in Mythology. See VANAMALI.

Gen. Ch. Col. Perianth inferior, of one leaf, cup-shaped, short, with five rounded marginal lobes. Cor. Petals five; regular, obovate, rounded, spreading, three to the length of the calyx. Stam. Filaments five, awl-shaped, dilated at the base, the length of the petals; anthers oval, veritable, incumbent. Fil. Germ. superior, ovate; style short and thick; stigma obtuse, nearly triangular. - Recept. befit with numerous brillers, about half as long as the stamens, surrounding the pistil. Peri. and sepal. unknown.

1. V. MADAGASCARIENSIS. - Native of Madagaftar, as its uncouth specific name denotes, where it was found by Commeron. The stem is arborescent, with alternate, cylindrical, smooth branches. Leaves simple, alternate, falced, obtuse, obtuse, entire, smooth, an inch or two long, with one rib and many finer transverse veins. Clyfters terminal, their partial flanks alternate, an inch or two in length, compressed, gradually, though slightly, dilated upwards, smooth, each bearing a little terminal head, of eight or ten small feline flowers.

VENANGO, in Geography. See Fort Franklin.

VENANGO, a county of Pennsylvania, containing eight townships, with 3060 inhabitants. Fort Franklin is the chief place. - Also, a township of Pennsylvania, in Crawford county, containing 474 inhabitants: the county contains 6178. - Also, a township of Pennsylvania, in Butler county, containing 377 inhabitants.

VENANT, St. See St. Venant.

VENANDUS HONORIUS FORTUNATUS, in Biography, a Chirlian poet of the sixth century, was born near Trivigi, in Italy, studied at Ravenna, and became eminently skilful in grammar, rhetoric, and poetry. Superficionally conceiving that he had obtained relief in a disorder of his eyes at the intercession of St. Martin, he wrote the history of that saint in verse. At Poitiers he was ordained priest about the year 1565, and afterwards elected bishop of that church. He is supposed to have died about the beginning of the seventh century, and an annual festival is kept at Poitiers in honour of his memory.

His works are mostly written in verse. His prose-writings are chiefly the lives of saints. Father Brower, a Jefuit, published his works in one vol. 4to. 1616, and they were also published by M. A. Luchi, at Rome, in 2 vols. 4to. 1786-87. His poems have found a place in the Corpor Poetarum of Mattaire. Nouv. Dict. Hilt. Gen. Biog.

VENASCA, or VENASCUS, or Benafia, in Geography, a town of Spain, in Aragon, on the river Ebro, in a valley to which it gives name, on the frontiers of France; 45 miles N. of Balbano.

VENASII, in Ancient Geography, a people of Asia, in Cappadocia. Strabo.

VENASQUE, in Geography, a town of France, in the department of the Vaucue, formerly the capital of the Venassin, on the Naque; 14 miles E.N.E. of Avignon.

VENCATIGHERRY, a town of Hindooftan, in Mysore; taken in 1791 by the Britifh, under captain Read; 51 miles E. of Bangalore. N. lat. 12° 57'. L. long. 78° 38'. - Also, a town of Hindooftan, in the Carnatic; 23 miles S.W. of Nellore. N. lat. 14° 3'. L. long. 79° 6'.

VENCATRAM, a town of Hindooftan, in Mysore; 25 miles E. of Hydooog.

VENCE, a town of France, in the departament of the Var. Before the revolution, the fee of a bishop, suffragan of Embrun; 6 miles N.E. of Graife.

VENCU, in Botany, the Chinefe name for an excellent fruit found in that country, which the Portuguese call jamboas, and the Dutch pompoenoe. It grows on prickly trees, like the limon-tree, only larger. Its flowers are white, exactly the fame in shape with thofe of the limon, and have an exceeding fweet smell; a very fragrant water is diffilled from them. The fruit itself far exceeds the citron
citron in bulk, being in size equal to, and sometimes exceeding a man's head; the rind is like that of the golden rennet; the pulp is of a reddish colour, and its taffie takes of sweet and acid, resembling that of grapes not fully ripe. A liquor is pressed from it, as in Europe from apples, pears, &c. It will keep for a whole year.

VENDEE, in Law, the perilon to whom any thing is sold, in contradistinction to vendor, or the seller.

VENDEE, in Geography, a river of France, which rises about eight miles N.N.E. from Fontenai-le-Comte, and runs into the Seve Niortois, about a mile E. of Marans.

VENDEE, one of the nine departments of the western region of France, formerly Lower Poitou, lying between Charente and Lower Loire, in N. lat. 40° 32'; bounded on the N. by the departments of the Lower Loire and Mayne and Loire, on the E. by the department of the Two Sevres, on the S. by that of the Lower Charente, and on the S.W. and W. by the sea. Its territorial extent is 7,442½ square kilometres, or 3,775 square leagues, and the number of its inhabitants is 270,271.

This department, watered by many copious streams, is one of the most fertile in France. It is divided by nature into the thicket, the marsh, and the plain. The first, so called on account of the great quantity of wood that covers it, includes nearly five-ninths of the whole territory. Its soil is of various qualities, yielding grain, wine, and excellent pastures. The second, lying on the W. and S. coasts, formerly covered by the sea, is impregnated with saline subfiances. Nevertheless it is fertile, producing plentiful crops of grain, flax, hemp, and pastures. The third is a fertile and well-cultivated strip of land, inclosed between the thicket and the S. border of the department. 

Bouin, an island containing about three square leagues, participates in all the qualities of the marsh. It was separated, not many years ago, from the main land by a narrow channel, which has now almost disappeared. Rainwater (which fees) is a fertile soil containing about three square leagues, opposite the city of Poitiers. It has a port capable of receiving vessels of fifty or sixty tons. But down on fine sand, near its N.W. coast, are frequently raised by the wind, and driven into the interior part of the island. Sfis Dieu is a very small island, covered with a thin bed of vegetable foil, mixed with sand, and not productive.

VENDELYA, in Ancient Geography, a town of Hispания Citerior, belonging to the Antirgones. Ptolem. 

VENDELION, in Geography, a town of the island of Ceylon; 64 miles N.E. of Candi. 

VENDEN, a mountain of the Tyrolese; 14 miles N.N.E. of Brixen.

VENED, a town of Ruffia, in the government of Riga, on the Aa. In the year 1572, Magnus, duke of Holstein, was brought to this town by Ivan Vafilikievitch H. cesar of Ruffia, to be made king of Livonia; but the new monarch was prevailed upon by his subjects, ever averse to the Russian yoke, to form a secret alliance with the king of Poland, and to counteract the cesar's progress in Livonia. Ivan, soon apprized of this negociation, laid immediate force to Venden, with fo numerous an army, that the inhabitants, finding all opposition ineffectual, proposed to capitulate. Magnus himself carried the terms of capitulation, and advancing to suplicate the incensed monarch, threw himself at his feet, and interceded for the town. The cesar, spurning at him with his foot, and striking him in the face, loaded him with reproaches for his ingratitude, and ordered him to prison; then entering the town, his troops committed every species of horror and devastation. Many of the principal inhabitants, retiring into the citadel, determined to defend it to the last extremity; but soon perceiving all Avitance to be fruitless, and expecting no quarter, they calmly assembled, received the sacrament, and then destroyed themselves, by blowing up the citadel; 36 miles N.E. of Riga. N. lat. 59° 12', E. long. 25° 14'.

VENENISES, in Ancient Geography, a town of Upper Moravia, at a distance from the Danube. Ptolem. 

VENDEVIL, in Geography, a town of France, in the department of the Aine; 8 miles S. of St. Quintin. 

VENDITIONI EXPONAS, in Law, is a judicial writ, directed to the sheriff, commanding him to sell goods, which he has formerly, by commandment, taken into his hands, for the satisfying of a judgment given in the king's court.

VENIDITORE REGIS, the king's scribe, or person who exposed to sale goods or chattels seized or disfrained to answer any debt to the king. This office was granted by king Edward I. to Philip de Lardimer, in the county of York, "Ita quod ipse, vel certus suus aturnatus, ibid mandatum viccomitis de loco in locum infra com. prad. summibus fuis, ad venditiones faciendas, & capitat de unaque venditione pro feudo tuo xxii. den.," but the office was feigned into the king's hands for the abuse thereof, anno 2 Ed. II.

VENEOUVRES, in Geography, a town of France, in the department of the Aube; 11 miles W. of Bar-sur-Aube.

VENDOME, a town of France, and principal place of a distriict, in the department of the Loir and Cher, on the Loir. Before the revolution, it gave name to a county in Beauce, called Vendomois; 7½ polls N.E. of Tours. N. lat. 47° 48'. E. long. 1° 8'.

VENDRE le Port, a small sea-port town of France, in the department of the Eastern Pyrenees; 12 miles S.S.E. of Perpignan.

VENDRELL, a town of Spain, in the province of Catalonia; 25 miles W.S.W. of Barcelona.

VENDRESSE, a town of France, in the department of the Ardennes; 9 miles S. of Charleville.

VENDUE, denotes an auction or public sale.

VENDUM, in Ancient Geography, the name of one of the four towns polised by the Scired, in the country that extended itself from the Pannomites to the Adriatic sea. Strabo.

VENEC, a town of Asia, in the interior of Media. Ptolem.

VENED, a people originally of Sarmatia, who occupied the whole coasts of the Venetie gulf, and who passed from thence into Germany with the Slav, where they inhabited the territory abandoned by the Germans. Jornandes says that these people, before that migration, had been vanquished and fubjugated by the barbarians, king of the Goths.

VENEDICI MONTES, mountains of European Sarmatia. Ptolem. 

VENEDICUS STYX, a post of the Baltic sea, in which were found the mouths of the Turusna, Crisna, Rubus, and Curon. Ptolem.

VENEDITOVA, in Geography, a town of Ruffia, in the
the government of Irkutsk, on the Amur; 8 miles E.N.E. of Nertchenkof.

VENEEING, Veneering, or Finessing, a kind of marquetry, or inlaying, by which several thin slices, or leaves of fine wood, of different kinds, are applied and fastened on a ground of some common wood.

There are two kinds of inlaying: the one, which is the more ordinary, goes no farther than the making of compartments of different woods; the other requires much more art, and represents flowers, birds, and the like figures.

The first kind is what we properly call veneering; the latter we have already described under Marquetry.

The wood intended for veneering is first fawed out into slices, or leaves, about a line thick: in order to faw them, the blocks or planks are placed upright, in a kind of fawing-press; the description of which may be seen under the article Press.

These slices are afterwards cut into slips, and fashioned divers ways, according to the design proposed; then the joints being carefully adjusted, and the pieces brought down to their proper thickness, with several planes for the purpose, they are glued down on a ground, or block of dry wood, with good strong English glue.

The pieces thus joined and glued, the work, if small, is put in a press; if large, it is laid on the bench, covered with a board, and pressed down with poles, or pieces of wood; one end of which reaches to the ceiling of the room, and the other bears on the boards.

When the glue is quite dry, they take it out of the press and finish it, first with little planes, then with divers scrapers, some of which resemble rasps, which take off dents, &c. left by the planes.

When sufficiently scraped, the work is polished with the skin of a sea-dog, wax, and a brush and polisher of havel-guts: which is the last operation.

VENELI, or Venelli, in Ancient Geography, a people who inhabited the maritime part of Lynnefe Gaul, and whose capital was the town of Crociatunum. Ptolemy.

VENELLIS. See Vicius & venelli mundandis.

VENENUM Cocry, a term used by many of the ancients for the purple tinge, which the kernels berry, as it is usually called (see Kerme), gave to linen, or other things.

The word Venenum being generally understood to express poison, it has been supposed by many, that the kernels were esteemed poisonous, or that there were two sorts of this drug: the one a harmful medicine, the other poisonous.

But there is no warrant for this in any of the old writers, and the whole feems indeed but a mistake about the sense of the word Venenum, which we find by many passages of the belt authors, signified a skin, as well as a poison.

The ancients called the vestments dyed scarlet with the kernels indifferently, by the names of Flammee or Venenate. Servius tells us, that in certain fared ceremonies, it was necessary that the priest should be clothed in a scarlet robe; and he uses the word Venenate to express it in some places, and Flammee in others.

VENER, one of the many names by which the chemists call mercury.

VENERE, Cape, or Capo di Venere, in Geography, a cape on the coast of Genoa. N. lat. 44° 4'. E. long. 9° 40'.

VENEREA Concia, in Natural History, the name of a very large and elegant genus of shells, more usually called porcellanei. See Porcelain Shell.

VENEREAL, something belonging to Venus.

A venereal poison is one addicted to venery, or venereal pleasures. Venereal medicines are called aphrodisiac, provocatives, &c.
all these ulcers, excepting the venereal, were well known to
Celsus, who describes with much accuracy in his chapter
de obserunum partium viitis all those ulcers on the genitals
which are mentioned by writers since the appearance of
syphilis as varieties of or anomalies in the venereal charac-
ter. Yet it is hardly credible, that almost to this day
there are writers who will conceive that local diseases, dif-
ferent in character in all their stages, in their mode of spread-
ing and healing, and requiring different modes of treatment,
must still be the same; who, while they admit that the ve-
nereal disease is of comparatively recent origin, will still
conform it with appearances most accurately described be-
longer than twelve centuries past.
Mr. Hunter, with that accuracy which distinguishes all
his remarks, began by fixing the character of the disease,
and even shewing, that from the laws of the economy, as
ascertained in all other local diseases, such must be the char-
acter of an ulcer arising from some external cause, and for
the cure of which animal economy had made no provision.
First: In every local irritation, he shewed that a secretion
of some fluid would take place, by which the irritating sub-
ject might be removed. The venereal matter, therefore,
irritating a solid part, induces ulceration, that the part may
rid itself of this irritating cause. But from the nature of
a morbid poison, the effect of that irritation is to pro-
duce a local action, by which a subflance is secreted similar
to that which induced the irritation. In some cafes, as in
small-pox, as soon as this effect is produced it ceases, and
the parts heal as readily as after any other loss of subflance;
but such is not the case with an ulcer from venereal poison.
When this is once set up, its action continues until some
subflance induces a more powerful irritation, and thus super-
fedes the venereal.
Secondly: When the curative process of a fore from any
cause is interrupted, it must spread, or a new action must be
set up. This new action, in common ulcers, is the formation
of thick, or, as they are usually called, callous edges, after
which the ulcer remains stationary. This was well re-
marked by Celsus, who gives this procfs the name of
netolias, describing the thickened lips, and remarking, that
whilst they continue, no applications to the ulcer are of
any use.
Thirdly: The peculiarity which distinguishes the venereal
ulcer from all others is, that the incapacity in the part to
alter the diseased action, produces the same effect as in
parts where there is any other impediment to healing;
namely, the thickened edge and base. But though the
attempt at healing is given up, still the irritation continues
from the constant presence of the virus, and consequently the
ulceration also, in order to rid the part of the cause of such
irritation. Hence we have what is not to be met with in
any other ulcer, namely, a continued ulceration, attended
with or accompanied by a hard edge and base. This is the
only true primary venereal ulcer, and the only ulcer or vitium
not described by Celsus in the chapter before alluded to.
The next question was, in what manner a disease incur-
able of itself was always relieved by mercury. For this a
thousand whimsical causes were assigned, the most common
of which was, that mercury was its antidote. This no one
could doubt, but did such an expression do more than affir-
men a word where we were looking for an action? At length
Mr. Hunter shewed, that this also was perfectly consistent
with what had been before observed; namely, if the venereal
ulcer is the effect of an action arising from the irritation
of a specific subflance, the cure must be effected by the
use of another subflance, the effect of whose irritation
would be greater than the irritation excited by venereal
matter; and the manner in which the disease always yields
to the remedy, confirms the doctrine. For no quantity
of this antidote, as it is called, will produce any effect on
a venereal ulcer, unless an excitement is induced greater
than the venereal: that is, if the chancre is recent, a very
flight mercurial irritation will be sufficient to alter its actio;
if more inveterate, the mercurial irritation must be excited
proportionally higher, and be longer continued.
It may at first seem that we have gained little, inasmuch
as we have now a more severe disease than before. But it
will readily occur, that the parts themselves are capable of
forming mercury, which is the cause of the initial irri-
tation, and which will continue all the action excited by that
irritation is superseded. But the parts are not capable of
forming mercury, by which the second irritation is induced;
we might therefore expect, as actually happens, that when
the use of mercury is discontinued, the action excited by it
would gradually cease also, and the parts be restored to
their original or healthy action.
But other difficulties remain. After the ulceration of
the genitals was perfectly healed, it sometimes happened, at un-
certain periods, that the throat, the skin, or the bones, or
all of them, would shew diseased actions, which, though very
different from those on the genitals, were equally incurable
without the remedy; and which, from their uniformity in so
many subjects, whether during the primary symptoms, or
after they were healed, evidently arose from the same cause.
The ignorance of former practitioners induced them to
suspect that these symptoms of confirmed pox, as they were
called, arose from an insufficient use of the remedy when the
chancre was healed. Yet it was impossible they should
be ignorant, that in many instances in which but compara-
tively little mercury had been used, none of these symp-
toms on distant parts of the body had occurred; and in
others in which the mercury had been used to a very
great extent, the patient had been a second or a third time
affected, though always in different parts, and with local
complaints, different from primary ulcers, yet arising from
a similar cause. Besides, if the disease occurred from the
want of a sufficient use of mercury, how did it happen that
the parts first affected should remain found, and parts not
previously showing any diseased action, should now become
in a state of open ulceration?
To account for this, Mr. Hunter shewed, that though it
is now well ascertained, that mercury will with certainty
cure every form of the venereal disease which we can
detect; it does not follow that it will cure it before such
an action has commenced, as evinces itself by some alteration
in the texture of the part; in other words, that it will super-
fede the venereal action by its higher irritation; but in order
to do this, the venereal action must have commenced. But
it is urged, that doubts thes the venereal action has com-
menced before we can trace it by our senses, and that there-
fore mercury ought in this state to supercede it, and to
prevent its arriving at open ulceration. In answer to that,
Mr. Hunter produces his facts, and shews that when the
action has appeared, it invariably yields to mercury, and
never appears again from the same source of infection in
the same order of parts. He taught us also what is now
universally admitted, that in the skin and throat it is always
curable by a much lighter course of mercury, than was
necessary for curing the primary chancre. Consequently,
if mercury could prevent the venereal action in these second
ary parts, the first course would prove sufficient for that purpose.
But the concurrent testimony of all the best writers goes to
prove, that none of them knew when to expect nor how to
pre-
prevent the appearance of the disease in more distant parts of the body, after it had been cured in the parts first affected; yet all knew how to cure it when it appeared in those distant parts. Boerhavë fancied he had discovered the cause of these difficulties, by comparing the solid texture of the bones with the more yielding condition of the softer parts. Both he and Dr. Swan were sensible how easy it was to cure the disease when it occurred in the skin and throat; but, as honest men, they were forced to confess their incapacity to prevent it, or even after they had cured it in those parts, to prevent its re-appearance in the bones, though in them also they could cure it with equal certainty after the diseased action had commenced.

An accurate attention to these events induced Mr. Hunter to construct a series of experiments, by which he might ascertain the laws which govern the actions excited by this poison, and thus meet all the difficulties of former writers. His first object was to fix the precise character of the chancre, or primary venereal ulcer. Having done this, he watched, by every possible means, those cases in which secondary symptoms occurred, and was convinced that it did not depend on any causes which could with certainty be controlled. This he urged was not different from many other morbid poisons. In inoculating for small-pox, no one can ascertain whether the patient will have pustules beyond the spot inoculated. Had he lived to witness the effect of cow-pox, he would have found a still more striking analogy. It is well known that secondary vessels from cow-pox, that is, a cutaneous eruption usually fourteen days after inoculation, and some few days after the inoculated part has scabbed, will sometimes appear at distant parts of the body; but we have no means of ascertaining under what circumstances these secondary eruptions occur, nor of preventing them, nor of producing them.

The conclusions drawn by Mr. Hunter were, firstly, that from every local action arising from a morbid poison, absorption takes place; secondly, that the absorbed virus circulates with the blood, and is ejected at some of the emunctories, probably the skin; thirdly, that for the most part it passes without contaminating any part in its passage; but that sometimes the throat, or the skin, or the bone, or all three are contaminated. In these cases the parts thus contaminated take the diseased action at certain periods, according to the nature of their structure, and the property of the morbid poison; for it is well known that few, if any, morbid poisons produce their effect till a certain period after their application. The small-pox effluvia are received usually from ten to fourteen days, before the disease shews itself; and the effect then commences on the face several days before the lower extremities exhibit any pustules. Under inoculation, the pustules on distant parts of the body appear at periods later than on the inoculated parts. But though every morbid poison requires a certain period between its application and the effect produced, and though this period is different in different morbid poisons, yet there is a medium in each; and Mr. Hunter ascertained, that the medium for the appearance of the secondary symptoms of syphilis is usually on the skin or throat, six weeks after the effusion of the irritation excited by the mercurial cure which cured the primary disease or chancre: that the appearance on the bones is usually three months after the same event; and that if the patient remains well longer than those periods after the healing of the chancre, he may for the most part consider himself free from any further danger from that source of infection. It must be admitted, that these periods are not always precise; but the same may be said of the small-pox, cow-pox, and other morbid poisons; and when we consider that the medium in one instance is from ten to fourteen days, and in the other from six weeks to three months, it must follow that the variations in each are not greater than their comparative medium would lead us to expect.

From these facts Mr. Hunter improved the practice in this disease so much, that we are often led to believe the disease itself to be milder than heretofore. But the truth is, that we now have some method in directing our treatment, which till his time could hardly be said to be the case. It was known, indeed, that mercury would prove a cure; but neither was the character of the disease accurately ascertained, nor the laws by which it yielded to the remedy, nor to which the secondary symptoms were imputable. Hence mercury was indiscriminately applied to all ulcers on those parts, and many were greatly exasperated by it; and as in the true disease secondary symptoms sometimes occurred, the patient was overwhelmed with a diffusing and deleterious remedy, to prevent what could not be prevented, though it rarely occurred; and when it did occur, was readily cured. But the mode of treatment was far from being the only advantage of Mr. Hunter’s discovery. By ascertaining the laws of the disease, he relieved the practitioner from every embarrassment, when secondary symptoms occurred; and the patient from the perpetual dread of an evil, from which it was supposed neither he nor his offspring were ever secure.

It is not to be wondered if the obscurity of Mr. Hunter’s mode of writing on a subject familiar to himself, but new to every reader, for a long time precluded the world from the benefit they have since derived from his discoveries. For this benefit we are indebted to Dr. Adams, and perhaps to those writers who attempted to controvert the doctrine itself. The latter were very numerous, and, as often happens, few were acquainted with the subject they opposed. Dr. Adams explained the difficulties principally by shewing the errors of his master’s antagonists, and at this time we believe the doctrine is universally admitted by all those who take the trouble to study it. That is, that the antidotal property of mercury consists in the high irritation it excites; that no ulcer on the genitals is phyllitic, unless it continues to spread with a hard edge and base; that it is useless to give mercury in order to prevent the secondary symptoms of the disease, either in the skin or bones, though that remedy will always cure them, if they should appear; and that if these secondary symptoms do not appear before a certain period after the primary ones, there is no reason to apprehend their appearing at all, unless the patient exposes himself again to the same cause. Such is the general doctrine of Mr. Hunter, divested of certain expressions, by which action is with more technical precision distinguished from diffusion. As this language is not necessary we have not introduced it, but refer such of our readers as wish to be acquainted with the precise terms of the discoverer, to the article Lues Venerea.

Dr. Adams has carried one of Mr. Hunter’s opinions somewhat further than the inventor. Mr. Hunter had observed, that after the venereal action of the primary ulcer was superceded by the mercurial irritation, new flakes would sometimes arise, but that it rarely happened that such new flakes would regularly cicatrice or heal. His commentator shewed that this was not peculiar to this disease, but extends to all morbid poisons; that in the small-pox and cow-pox it produces the pitting from the fifth, and indentation from the second; and that in all other morbid poisons where there is a loss of substance, that loss is never restored by the common means

VENEREAL VIRUS.
means of incarnation, called granulations. That if such an attempt is ever made it produces a fungus, called by Mr. Hunter new flesh, which will not heal, and which requires the application of caustic before any attempt at skinning will commence. After this application, Mr. H. remarks the readiness with which the whole will skin over. In this language, the surgical reader will observe the caution with which Mr. Hunter avoids the common terms of granulation and cicatriseation, by substituting for the first new flesh, which will not heal, and for the second, skinning, which rapidly takes place over the whole form, whereas it is well known that cicatriseation is the most tedious part of the healing process in all other ulcers. In this manner the writer of this article conceives we are to reconcile ourselves to that remark on the granulating property of chancre mentioned under the article Lues Venereal; which see. See also Morbid Paffions.

VENERA, or Aphrodithsium, Paradise, in Ancient Geography, a town of Africa, situated on the sea-coast, N.N.W. of Adrumetum. Ptolemy.

VENERIE, or, in Geography, a town of France, in the department of the Po, which took its name from a royal palace built by Emanuel II. Duke of Savoy, for a hunting seat: in this town are carried on manufactures of wool and silk. The palace was magnificent, and the adjacent country abundant with game; 3 miles N.N.W. of Turin.

VENERIS, Ac putas Templum, in Ancient Geography, the name of a temple built by the Trojans in honour of Venus, when they landed on the coast of Epirus, and took possession of the peninsula called Leucas. Dion. Halie.

This temple was on the promontory of Aetium.

VENERIS, Ariones Fanum, a temple of Egyptian, on the promontory Zephyrium, between Canopus and Alexandria. Strabo.

VENERIS, Aures Campus, a territory of Egyptian, in that of Memphis. Dio. Sic.

VENERIS, Infusa, an island of the Arabic gulf, on the coast of Egypt. Pliny.

VENERIS, Lacus, a lake situated, according to Pliny, at Hierapolis in Syria. It was a marsh, near a temple of Juno, according to Lucian.

VENERIS, Mors, a mountain of Spain, S. of the Tagus, and near the country of the Carpetani, according to Appian.

VENERIS, Portus, a port of Gallia Narbonensis, on the Mediterranean sea, between the promontories of the Pyrenees, and N. of Cervaria. This port was famous for a temple of Venus.—Alfo, a port of Italy, in Liguria, on the confines of Etruria, between Segelta and Portus Delphini. Anton. Itin.—Alfo, a port of Egypt, upon the Arabian gulf. It was anciently named "Myos Hornes," or "Muras Statio," also called "Magnus Portus," and afterwards "Veneris Portus," according to Ptolemy, who says that it was near the promontory Drepanum.

VENERIS, Effrum, the stimulus or incentive of venery, is an apellation given, by some anatomists, to the clitoris.

VENERIS, Effrum, is also used, by others, for the transport of love, or the utmost and agreeable enjoyment in copulation.

Some are of opinion, that infectious women are the most apt to communicate the poison when they are thus excited with desire; whereas, with indifference, they may admit the name intercouerce, without giving the infection.

VENERIS, En. See En.

VENEROUE, in Geography, a town of France, in the department of the Upper Garonne; 10 miles S. of Toulouse.

VENERY is used for the act of copulation, or coition, of the two sexes.

It takes its name from Venus, the supposéd deity of the passion of love.

VENERY also denotes the art or exercise of hunting wild beasts; which are also called beafts of venery, and beafts of the forest.

Such are the hare, hart, hind, boar, and wolf. See Beast, Game, and Hunting.

VENATION, in Surgery, the operation of opening a vein, for the purpose of taking away blood for the relief of dyspepsia. See Bleed.

VENESS, in Geography, a cape on the S.E. coast of the island of Eady. N. lat. 59° 1'. W. long. 2° 38'.

VENETA BULLS, a fine red earth used in painting, and called in the colour-shops VENETIAN RED. See RED.

It is improperly denominated a bode, being a genuine species of red ochre. It is of a fine bright, and not very deep red, approaching, in some degree, to the colour of minium, or red-lead, and is moderately heavy, and of an even and smooth texture, yet very friable, and of a dusty surface: it adheres firmly to the tongue, is very smooth, and soft to the touch, easily crumbles to pieces between the fingers, and very much stains the skin in handling. It has a slight alrignant taste, effervesces considerably with aqua balsamica, and in water immediately breaks into a fine powder.

It is dug in Carinthia, and sent from Venice into all parts of the world, being an excellent colour, and very cheap: our colourmen, however, find too many ways of adulterating it. Hill and Da-Coca.

VENETI, in Ancient Geography, a people of Italy, in Venetia, of Celtic origin. According to some historians they were the descendants of a colony of Trojans, who came to embellish themselves here on the ruin of their own country; but Herodotus says that they were an Illyric nation.—Alfo, a people of Gallia Celtica, in Armorica, who inhabited the peninsula above the Nannetti, according to Caesar (De Bel. Gall. lib. iii. e. 8.) who ascribes to them the glory of being the most powerful of all the people who inhabited this coast, and who availed themselves of their shipping, and of the science and practice of navigation. Ptolemy calls their capital Dariorigum. Caesar denominates their territory Venetia, although the Veneti, who inhabited that promontory of Gaul which is now called Britain, excelled, as Caesar says, all the nations on the continent in their knowledge of maritime affairs, and in the number and strength of their ships; yet, when they were preparing to fight a decisive battle against the Romans by sea, they asked and obtained auxiliaries from Britain; which they certainly would not have done, if the Britons could have assisted them only with a few lighter-boats, covered with skins. It is therefore probable, that the people of Britain had ships much of the same form and construction with those of their friends and allies the Veneti, with which they joined their fleet on that occasion. These ships of the Veneti are described by Caesar as very large, lofty, and strong, built entirely of thick planks of oak, and so solid, that the beams of the Roman ships could make no impression upon them. The combined fleets of the Veneti and Britons, in the famous sea-fight off the coast of Armorica, now Britain, against the Romans, consisted of two hundred and twenty of these large and strong ships, which were almost all destroyed in that unfortunate engagement; by which the naval power both of Gaul and Britain was entirely ruined. This great disaster is believed, by some of the best of our antiquaries and historians, to have been the reason...
reason that the Britons never attempted to make any
opposition to Caesar by sea, when the very year after it he in-
vaded their country.

VENETIA, a country of Italy, which commenced E.
of Gaul, near the lake Benacus, and the river Minexus,
which flowed from it. Its boundaries to the N.E. were
not very distinctly ascertained. Its principal rivers, before
the Po, were the Atheitis, the Medocas Major, and the
Plavis. It was very fertile in pasture, and furnished ex-
cellent horses. The people were denominated Veneti or
Heni. Their principal towns were Hadria, Atlette,
Patavium, Verona, Vicentia, Altinum, Tarvisium, &c.
See Venice.

VENETICÆ Insulae, or Veterorum Insulae, compre-
prehended, under this denomination, a great number of islands
situated on the western coast of Gallia Celtica or Lyonsensi.
This general appellation included Bellile, Houat, Hedic,
Groa or Gronias, now Quiberon. These islands occupied
that part of the sea which was opposite to the continent
inhabited by the Veneti; which fee.

VENETO, in Geography, a small island in the Medi-
terranean, near the coast of the Morea. N. lat. 26° 41'.
E. long. 25° 53'.—Alfo, a small island in the Grecian
Archipelago, near the S. coast of the island of Scio.

VENETORI, a town of Walachia; 24 miles W. of
Bucharest.

VENETUS Lacus, in Ancient Geography, the name of
one of those two lakes, which the Rhine formed near its
source in the Alps. The lake now called Boden-fee, or
more commonly the lake of Constance, is called " Brigant-
inus" by Pliny, and " Brigantia" by Ammianus Mar-
cellinus. Strabo assigns to it 330 stadia of length, and 200
of breadth. Its name Boden-fee is derived from a place
called Bodman, situated at the extremity of the lake oppo-
site to which is Bregenz, whence the appellations Brigantia
and Brigantinus.

VENEV, in Geography, a town of Ruffia, in the govern-
ment of Tula, on the Ofer; 40 miles N.N.E. of Tula.
N. lat. 53° 20'. E. long. 36° 14'.

VENEV. See Vene.

VENEZIANO, Antonio, in Biography. Of this early
painter, his birth-place is not exactly known, as he is by one
author supposed to have been a Venetian, and by another
a Florentine. His principal works are at Pisa and Florence,
and in the Ducal palace at Venice. He certainly improved
upon the style of those painters who preceded him, if we ex-
cept Giotto; his manner was less formal, and he is said to
have painted well in fresco, and to have carried the manage-
ment of it to a considerable degree of perfection. He died
in 1384, at the age of 74.

VENEZIANO, Domenico, was born at Venice in 1420,
and was a disciple of Antonio da Meffina, after he had, as
Vafari relates, learned the secret of oil painting from J.
V. Eyck; and to him Meffina communicated his secret.
He painted several pictures at Loretto and Perugia, and
afterwards settled at Florence; where the novelty of his
manner, and the ability with which he executed it, acquired
for him considerable renown. Unfortunately for him, he
formed an intimacy with Andrea Callagno, an eminent
Turcan painter, and taught him the management of oil
colours; when his treacherous friend conceived the hor-
rible design of affailing him, that he might remain
sole poiffor of the secret, and effected his detestable
purpofe in 1476, when Domenico had attained his 56th
year.

VENEZIANU, Antonio, a Sicilian poet, was born in
1543, at Monreale, and acquired great celebrity in science
and polite literature, so that it was fashionable to cultivate
acquaintance with him; and amongst those who fought this
honour was Tafo. In 1578 he was taken, on a voyage to Rome,
by an Algerine corsair, but redeemed; on his re-
turn to his native country, he was imprisoned under a sus-
picion of being the author of some writing against the
vicey of Sicily, and being confined at Palermo, he was
destroyed in the castle by the explosion of a powder-
magazine in August 1593. His writings confifth chiefly of
sonnets and lyric poems in the Sicilian dialect; and some
of his compositions in pure Italian were printed at Palermo in
1572. A large collection of his Sicilian poems exists in

VENEZUÉLA, in Geography, a province of the eastern
part of Terra Firma, or of Spanish America, included within
the jurisdiction of the captain-generalship of Caracas, which
is not only the capital of this province, but the metropolis
of the captain-generalship, the seat of the royal audience and
of the intendancy, while authority extends over the provinces
of Venezuela, Maracaibo, Vinaras, Cumana, Guianas,
and the island of Margareta; extending from N. lat. 12° to
the equator, and from 62° to 75° long. W. from the meridian
of Paris. The name of the province, which is in Spanish a diminu-
itive of Venice, was given to this province on account of some
Indian villages, which the first conquerors found on the
lakes of Maracaibo. Others have erroneously ascribed
the origin of this name to the following circumstance; viz.
that Alphonso Ojeda, having landed here in 1499, caused
some huts to be constructed upon poles, in order to elevate
them above the flagnant water which covered the plain;
but though it is true that Ojeda, in 1499, visited the
eastern shore of Terra Firma, he never thought of erecting
any huts over its flagrant waters. The chief place of the
province of Venezuela has never been nearly on a level
with the water. Caracas is at least sixty toises above the level
of the sea, and has no other water besides that of three brooks
which pass rapidly through it, and of a small river which
bounds it on the south. The first settlement of the Spa-
NIARDS on the borders of the lake of Maracaibo took place
in 1527. The population of Venezuela, including Vinaras,
confined, in 1801, of 500,000 persons; that of the govern-
ment of Maracaibo, of 35,000; of Guianas, 34,000; and of the
isle of Margareta, 14,000: making a total, according to the statement of Depons, of
728,000. The population of Caracas, in 1802, is stated at
from 41,000 to 42,000, consisting of whites, slaves, freed
persons, and very few Indians; the first classes forming nearly
a fourth of the whole, the slaves a third, the Indians a twen-
tieth, and the freed persons the rest. All the whites are either
planters, merchants, military men, priests, monks, or persons
employed in the administration of justice or finance. In
this population, the whites are computed at two-tenths, the
slaves at three, the descendants of freed-men at four, and the
Indians compose the remainder. A late writer, professing
himself a "South American," in his "Outline of the Revolu-
tion in Spanish America," (1817,) says, that in the town of
Caracas alone there were 45,000 inhabitants; and the whole
population of Venezuela, including the several provinces
above enumerated, amounted in 1811 to more than 820,000.
The soil of Venezuela is fertile, and yields, with prodigal
liberality (says Depons), all the productions which are
of value with the West India islands, besides many
others which they do not possess. If a man labour, he must
grow rich; and if he vegetate merely in idleness and sloth,
he has only to flrov, in order to gather from the foil more
than sufficient to satisfy the wants of nature. The cacao of
this province is abundant and excellent. It likewise fur-
ishes
VENEZUELA.

nishes Indian corn, indigo, tobacco, cotton, sugar and coffee. Its vanilla, produced from a creeping plant, which, like the wild vine and ivy, entwines round the trees, is obtained in great plenty. Wild cochineal is also the product of this country, and with due cultivation, it might be made to furnish a variety of woods, barks, and plants for the dyer; and also gums, refining of balsam and medicinal oils; its farfparilla is said to exceed the consumption of the whole of Europe; falfafra and liquorice abound; squills are plentiful; so are likewise florax, cattis, aloes, &c. The horned cattle, affording the article of exportation (hides), the horses, mules, sheep, and deer, are here very numerous. It abounds in all kinds of game, and its rivers and lakes supply plenty of fish.

In order to give a brief account of the revolution that has lately taken place in this province, and in other parts of Spanish America, we shall trace the origin and progres of the Spanish establishments in this part of the world. Terra Firma was discovered by Christopher Columbus in 1498, in his third voyage from Spain to America. After having discovered the gulf of Paria, he coasted along Terra Firma as far west as the Tegito islands, from which point he failed with a fair wind to St. Domingo. Ojeda obtained permission from the Spanish government to pursue the discovery; and having arrived at the territory of Maracapna, in the year 1499, he followed the coast as Cape de la Vela, entering several ports in order to collect more minute information. From Cape de la Vela he failed for St. Domingo, according to Oviedo and Robertson; but according to Charlevoix, he returned before that to Maracapna, a village upon the coast of Cumana, and there had a brig built. Not long after, the account which Columbus had given to the Spanish government attracted to Terra Firma another vessel from Spain, whose real object was commerce, but which concealed its design under a permission from the king to prosecute the discovery of the country. This vessel, commanded by Christopher Guerra, touched on the coast of Paria, at Margarita, Cubagua and Cumanagota, now called Barcelona. In these places, in exchange for trinkets, he obtained a great quantity of pearls, gold, Brazil wood, &c. of which he formed a very rich cargo. Guerra pursued his course along the coast to the westward, and landed only at Coro, where he found, to his great astonishment, some Indians, as much disposed to take away from him whatever he had got, as those on the eastern coast had been to give them to him. He had too much to lose to run the risk of a war, by which neither glory nor emolument was to be acquired. He, therefore, wisely took the resolution of returning to Spain, in order to place his riches out of the reach of danger.

The report of his arrival and fortune spread over the whole kingdom, and immediately from every part expeditions were fitted out for Terra Firma. At the same time, Charles V. gave permission to make slaves of the Indians who should impede or embarrass the conquest; a grant so much the more deplorable to humanity, as it strongly excited the avarice of those in whose hands money chiefly held the place of every other consideration. It is easy to imagine, that upon those coasts, where tillage had nothing to fear either from the vigilance of the magistrate, or the war of pirates, there must have been established a notorious commerce, which had no other object than infeatable avarice, no other result but rapacity, tyranny, and ferocity. The crimes committed by that swarm of robbers, who contended with one another for superiority in feats of plunder, were so great and so numerous, that the cries of the victims reached the audience of St. Domingo, who are entitled to our applause for having immediately taken measures to make it appear to the inhabitants of the new world, whom they wished to lead rather than to drive into obedience, that the enormities of that feast of the Spanish nation were not properly chargeable on the nation itself. The audience sent thither, in quality of commissary and governor, a man of very great merit, named John Ampues, who arrived on the Coriana coast in 1527, with sixty men. His mildness, affability, and knowledge soon gained the confidence of the cacique of the Coriana nation; and a solemn treaty confirmed the union and alliance which they formed, and the cacique took the oath of allegiance and vassalage to the Spanish monarch. On the 27th of July, 1527, Ampues laid the foundation of Coro. Thus the province of Venezuela had the pleasing prospect of arriving, without commotion, to a degree of prosperity which would crown the happiness of its inhabitants. However, the commercial house of the Welfers, established at Augsburg, being considerably in advance to Charles V., and who, with the treaty made by them, patroons of the natives, the king refunded, and the emperor appointed governor the licentiate John Pérez de Tobón, who, according to Oviedo, had likewise the title of captain-general. This new reformation produced a favourable change in the system and mode of conquest; and it was an established point, that instead of committing devastation, the conquerors should form settlements; and instead of plundering, respect property. Laws, which had been enacted in 1526, 1540, 1542, 1550, and 1552, were put into execution. These laws declare the Indians to be free, not even excepting those who should be taken prisoners in the act of bearing arms. As soon as an Indian nation was subjected to the Spaniards, a convenient fite was chosen on which to build a town, for the better security of the conquest. One hundred Spaniards formed the population of the new city, to which a cabildo was attached. They afterwards divided the city in portions among the new inhabitants, according to their rank and merit; and after having made an enumeration of the Indians, they shared them among the Spaniards, who thus acquired over them a right, not of property, but of superintendence. This is what is called "repartimientos de Indios," the dividing of the Indians. This measure was followed by more fixed regulations, under the name of "encomiendas;" the effect of which was to place under the immediate superintendence and authority of a Spaniard, exemplary for his morals, the Indians who lived within a limited extent of ground, corresponding to that of the communes in France. In return for these attentions, the Indians were to pay the commisioned superintendents of the encomiendas, who were called encomenderos, a yearly tribute in labour, fruits, or money. When this tribute was once paid, the Indians were exempted from every other personal service. It appears that, according to the voluminous and special contract entered into between the kings of Spain and the discoverers, conquerors, and settlers in Spanish America, politically divided by the Spanish government, and comprehending the viceroyalties of New Spain or Mexico, Santa Fé de Bogota or New Granada, Peru, Buenos Ayres, or the province of Rio de la Plata, and the captain-generalships of Guatemala, Venezuela, and Chili; these last were to remain lords of the country, on the hands of feudal vassalage, under the names of "encomenderos." Such, however, was the inhuman conduct of the first of these towards the natives, that Charles V. and his successors were under the necessity of
of gradually abolishing many of their privileges, and the

"encomiendas" fell at length, in most of the provinces, to
the crown; and certain inferior privileges were then
granted to the settlers, in lieu of those originally possesed,
with the titles of marquis, count, &c. Spanish America
was from that time considered as a kingdom, independent in
itself, yet united to Spain, as being both under the govern-
ment of one king. The incorporation of this country to
the crown of Castile was decreed by Charles V. in Barcelona,
September 14, 1519, and confirmed by Donna Juana, Phi-
lip II. and Charles II. Accordingly, in the opening of the
royal decree published in the year 1524, for the nomination
of a supreme council for the Indies, the term kingdom is
expressly used, and its use admits, that the inhabitants had a
natural right to hold the appointments of profit and honour
in the country. The energetic remonstrances of Montefino,
Cordova, Las Casas, and others, to the court of Spain,
against the arbitrary measures of the conquerors and settlers,
gave rise to the establishment of the Council of the Indies.
(See Council of the Indies.) Whilist the legislative power of
the kingdom of the Indies rested in this council, and the
king, the executive power belonged to the viceroys and cap-
tain-general. The viceroys were also invested with royal
powers, that is, they were authorized by a special commision
with plenitude of power in extraordinary and delicate
emergencies.

From the most exact calculations, it is concluded that the
continental part of Spanish America contains thirteen millions
of inhabitants; part of which population is employed in
agriculture, particularly in Venezuela, Guatemala, Gua-
ayquil, Chili, Carthagena, &c.; and many in the care of
cattle, especially in the provinces of Rio de la Plata and part
of Venezuela; while the inhabitants of several provinces of
Mexico, Peru, and New Grenada, are almost wholly em-
ployed in working the mines. The Indians and Negroes
have retained, in a great measure, their primitive customs;
the Creoles have received theirs from the Spaniards.
The Catholic religion being that of Spanish America, the church
and government are ecclesiastical dignities are the same as in the
mother-country. The inquisition was also established in the
new continent; all access to the Spanish settlements was not
merely closed against foreigners, but even the inhabitants of
the different provinces were prohibited from intercourse with
one another. Commerce was exclusively carried on with
Spain, and was almost entirely in the hands of Spaniards;
about the end of the last century, however, some special
privileges were obtained from the viceroys and captains-general
to trade with the Antilles, when communication with the
mother-country was very difficult; and in 1797 the court of
Madrid was obliged to allow some of the ports of Terra Firma
to be opened for the advantage of commerce. Urged by
similar motives, Ciferos, the viceroy of the provinces of Rio
de la Plata in 1809, opened the ports of Buenos Ayres, that
a free trade might be carried on with the nations in alliance
with Spain.

The court of Madrid long maintained its power in the new
continent, by a small number of Spanish troops, as the
Creoles were cordially attached to the mother-country, and
the Indians unable to free themselves; but about the middle
of the last century, a plan of conspiracy was formed in Ca-
racas, with a view of destroying the company of Guipu-
cos, to which the privilege had been granted of exclusively
trading with Venezuela. The design was discovered, and
the head of the conspiracy condemned to death. (See Car-
racas and Guipuicos.) The oppressions of the repartimien-
tos, and other grievances, gave rise also to the insur-
reccion which took place in Peru in 1780. By the syflem of
the repartimientos, the Indians were obliged to receive their
necessary supplies of goods, hardware, and mules from the
corregidores (officers named by the king), at the prices they
fixed, and on the credit they thought proper to give. In
1781, some reforms and additional taxes were introduced
in New Grenada, in the province of Socorro, one of the most
populous of the viceroyalty; but the province openly
declared against these changes, and having assembled near
17,000 men, marched against Santa Fe de Bogota, ex-
claiming, "Long live the king, but death to our bad

Some few Creoles and Spaniards, well acquainted with the
principles laid down by the French politicians in the early
period of the French revolution, and with those of the
writers who preceded that period, formed a plan for revolu-
tion in Caracas in 1797. They treated the Spanish govern-
ment with contempt, and trusted to the protection of the
English, in consequence of Mr. Pitt's well-known plan of
giving independence to Terra Firma. The conspiracy was
discovered, and theensonable leaders made their escape; but
one of them was afterwards apprehended and hanged. Sir
Thomas Picton, governor of Trinidad, issued at this time a pro-
claimation, in which he says, towards encouraging the
inhabitants (of the continent near to Trinidad) to refil
the oppressive authority of their government; "I have little
more to say, than that they may be certain, that whenever
they are in that disposition, they may receive all the
favour to be expected from His Britannic Majesty, be it
with forces, or with arms and ammunition to any extent;
with the assurance, that the views of His Britannic Majesty
shall go no further than to secure to them their independence,
without pretending to any sovereignty over their country,
nor even to interfere in the privileges of the people, nor in
their political, civil, or religious rights." To afflit the revo-
olutionary party in Spanish America, the English cabinet is
said to have paid the expedition of Miranda to Venezuela in
1806, and to have sent that of Whitelocke to Buenos Ayres
in 1807, both of which failed. It is certain that the inhab-
abitants of Spanish America have been long discontented, and
that they have complained of various grievances to the court of
Madrid. This court, however, knew how to answer petitions
without redressing grievances. But Napoleon Bonaparte,
when he became in fact master of the Peninsula, and possessor
of the wealth of America by the influence he had in this
court, having invaded the kingdom and seized the royal
family of Spain, loofened those bonds which united the new
to the old world, and gave rise to a revolution which, from
the wide extent of the country in which it is seated, its char-
acter, and its consequences, is unparalleled in the annals of
history. When Bonaparte had not only invaded the king-
dom, but feigned king Ferdinand, and assemblies under the
denomination of "juntas" were established in various pro-
vinces of Spain, each assuming in its respective district the
supreme authority, the Spanish Americans were perplexed
and dubious as to the conduct which they ought to pursue.
The moment for freedom seemed at length to preferit itself,
after they had been wearied and exhausted by a series of
f uguffings for three centuries. However, Spanish America
was still attached to the mother-country; and when it was
announced at Caracas, in July 1808, that Joseph Bonaparte
had taken possession of the Spanish throne, the city was
immediately in arms; 10,000 of its inhabitants surrounded the
residence of the captain-general, and demanded the pro-
clamation of Ferdinand VII. as their king; which he pro-
mised to do next day. But such was their ardour, that they
proclaimed him that evening by heralds in form, throughout
the city, and placed his portrait, illuminated, in the gallery
of
of the town-house. Some months after this wonderful display of attachment to the mother-country and its sovereign, many respectable families of Caraccas concurred in presenting a petition to the captain-general, Cafa, for permission to elect a junta similar to those in Spain. The petitioners indeed were arrested; but after a confinement of very few days they were released. About the end of July, 1808, Liniers, viceroy of Buenos Ayres, received intelligence of the events that had occurred in the Peninsula; and in a proclamation addressed to the people, he exhorted them, in the name of Bonaparte, to remain quiet. Xavier Elio, the governor of Monte-Video, accused him of dilatoriness, and thus separated the country under his command from its allegiance to him, by forming a junta resembling those of Spain.

The news of the general insurrection in Spain reached Mexico on the 29th of July, 1808; and a junta was immediately established. La Paz, which was the capital of one of the districts under the dominion of the audiencia of Charcas, considering Spain too feeble to free herself from the power of the French, wished to provide for its own security; and, in the beginning of the year 1809, formed a government for itself, composed of many respectable persons, which was styled "junta intitulica." The viceroy of Buenos Ayres sent an army to oppose this motion; and Goyeneche, marching, by order of the viceroy of Peru, against La Paz, who succeeding, ordered numbers of the patriots to be ignominiously and cruelly executed. Quito, nevertheless, capital of the audience bearing its name, established a separate government, August 15th, 1809. But the viceroy of Santa Fe de Bogota hastened to destroy the junta of Quito by force of arms; and Abacal, the viceroy of Peru, did the same. The defenders of the junta were obliged to yield to superiority of force, receiving a promise from the Spanish president of Quito, that past events should be forgotten. But regardless of this promise, many patriots, amounting to more than 300, were murdered in cold blood. In 1810, the junta of Caraccas commemorated the fate of these victims with funeral honours equally magnificent and solemn. Upon the dispersion of the central junta in Spain, and an illegal election of a regency, the inhabitants of Caraccas resolved to try to obtain by force what reasonable representation had failed to gain for them. The municipal body, in conjunction with many persons named by the voice of the people, assumed the reins of government, and the appellation of "junta suprema." The acts of the junta were published in the name of king Ferdinand VII.

The establishment of the junta of Buenos Ayres was effected with more tranquillity than that of Caraccas. A junta was formed at Chili in September; and disaffection, occasioned in Mexico by violent measures, produced an insurrection, September 16th, 1810, in the town of Dolores, near Guanaxuto; which insurrection soon extended through the whole country.

When the council of regency received intelligence of the proceedings at Caraccas, by which the inhabitants declared themselves independent of the mother-country, and determined upon forming a governing junta to exercise this sup­posed independent authority, it resolved to adopt vigorous measures for preventing the progress of this evil; and, for this purpose, consulted the council of Spain and the Indies. Accordingly the regency declared the province of Caraccas in a state of rigorous blockade. The measures now adopted evinced the prevalent spirit that actuated the Spanish Americans, though the different provinces were not acting in concert with each other. War seemed to be the will of the merchants of Cadiz, and of the cortes that had been assembled by the regency; and various methods were used to excite and encourage it. Its long continuance, and the savage manner in which it is prosecuted, evince the irreconcilable animosity of the contending parties. "The Spaniards fight for reconquering their once proselized territories, and the Spanish Americans to obtain independence: the first are cruel in the hour of triumph, and with adversity their en­mity increases; the latter are courageous in attack, and, when defeated, ready to place confidence in their leaders, and to rally under their banners. The first possess great military skill; the latter, superiority of number. Both have uniformly shewn a firmness and decision in action suited to the high objects they have in view, and to the great obstacles they have to overcome. In these contests, the blood of thousands has already inundated an extent of country of more than 1600 leagues, which comprise the Spanish settlements in the new continent; and as if the mortality in the field of battle were not sufficient, numbers are daily murdered in cold blood."—"The Spanish chiefs and rulers, it is said, gave the first example of violating capi­tulations, of shooting prisoners, and of refusing all means of accommodation, in the cruel war carried on in the new continent, by the authority of the cortes of Spain, and by Ferdinand VII. The old Spaniards of either world must be altogether unable to find an excuse, or even a palliation, for their want of humanity, and breaches of faith, since the beginning of the revolution. The cruelty of the Spanish chiefs, and tokens of approbation on the part of the regency and cortes, have exasperated the newly-formed governments in Spanish America, and given strength to their decisions. At first the revolutionary spirit was confined to very few persons, but it soon spread through the whole continent. This sufficiently appears in the spirit and language of the act of independence published by the congress of Caraccas, July the 5th, 1811. Similar declarations to those of the congress of Venezuela were made in Mexico, and in Carthagena, Socorro, Tunja, Pamplona, Antioquia, and the other provinces, which composed the confederation of New Grenada, and more lately by the congress of Buenos Ayres." When king Ferdinand, in his decree of the 4th of June, 1814, announced to the South Americans his return to his country, he ordered that they should lay down their arms; and this order was enforced by an army of 10,000 men, equipped at Cadiz, and placed under the command of Morillo. This army appeared on the coast of Venezuela in April, 1815. All hopes of reconciliation were now abandoned, and a revolt in Spanish America against Ferdinand VII. may be dated from this period. From Camapo general Morillo proceeded to Margareta, and from thence to Caraccas; and in the following August he besieged Carthagena. Although difficulties had occurred between Bolivar and Cabello, both commanders of the South American forces, and left them the means of defence which Carthagena possessed, the inhabitants, nevertheless, supported by nearly 2000 regular troops, prepared for a vigorous resistance. But provisions failed, and more than 5000 persons died of famine. On the 5th of December, 1815, the governor and garrison of Carthagena evacuated the place, and on the following morning the king's troops entered. General Morillo, thus possessed of Carthagena, was enabled to conquer New Grenada. He entered Santa Fe de Bogota in June, 1816, and remained there till November. More than 600 persons of those who composed the congress and provincial governments, as well as the chiefs of the independent army, were shot, hanged, or exiled; and the prisons were full of others waiting their fate.

The first decree of the junta suprema of Caraccas, formed
April 19th, 1816, contained orders to arrest the captain-general, and the members of the audiencia, who were sent to the United States of America: it was decreed that the alacabals, or duty on selling any commodity, should be aboli-
hished, the tribute paid by the Indians, and the slave-trade; that freedom of commerce, agriculture, &c. should be estab-
lished; and that these political changes should be made public, and communicated to the English government. Juntas were formed for similar purposes in different prov-
ces. The regency of Spain was incensed, and it declared all the ports attached to the new government to be in a state of blockade; and orders were given for reducing
Venezuela to its former subjection. When these orders proved inexpedient, fates and emigrations of every description
were sent to all parts of Venezuela, for the purpose of
effecting a counter-revolution. General Miranda reached
the shores of Caraccas in the end of 1810, notwithstanding
the instructions given by the junta supreme for opposing the
return of the general to his native country, with a view of
evincing the moderate plan of conduct which the junta had
adopted towards Spain. A general congress met, and the
plan of a confederation, as the best fort of government for
Venezuela, was formed and adopted. Miranda, however,
opposed it, and his conduct gave offence. In April, 1811,
the congress nominated three persons, who were to consti-
tute the executive power, which was very limited. Al-
though several persons were secretly devious of reunion with
the mother-country, they durst not avow it, so earnest
were the inhabitants of Caraccas for independence. The
anniversary of the revolution, on the 19th of April, was
kept with great rejoicings. A molt alarming conspiracy
was just ready to break out in June, 1811, but it was dis-
covered and defeated. In the midst of the prosperity of
Venezuela, it was visited, March 26th, 1812, by a most
tremendous earthquake, which destroyed nearly 20,000 per-
sons. The towns of Caraccas, La Guayra, May-
queta, Merida, and Sanfelipe, were totally demolished; and
Barquisimento, Valencia, La Victoria, and others, suffered
very considerably. At this crisis, general Miranda had the
command of the army, and general Monteverde commanded
the royalists. Caraccas at length fell under the power of
the royalists; the republican army was disband ed; and Mi-
manda, with many others, proceeded to La Guayra, intend-
ing there to embark for Carthagena. But Miranda was
betrayed, and he, with nearly 1000 patriots, were thrown
down into dungeons at La Guayra and Puerto Cabello. In con-
sequence of this disfaster, Cuchana and Barcelona acknowl-
dged the authority of Monteverde; and other similar
events occurring, the Spanish government renounced its au-
thority in Venezuela. Vengeance filled the mind of Mont-
everde. The Spaniards thought, by destroying the in-
habiting of Venezuela, the first province which had shaken
off their yoke, to punish in them the insurrection of the
whole southern continent. Every royalist became a public
accuser; every prisoner was filled with patriots; and al-
most the whole population were under confinement. This con-
duct of the royalists, instead of conciliating, excited the
hatred of the inhabitants; and the courage of those who
were attacked to the cause of independence revived. The
province of Cumana first opposed the oppression of Monte-
verde; and here he was twice defeated. Don Simon Bo-
lovak, one of the most distinguished natives of Caraccas,
obtained from the congress of New Grenada near 600 men;
and with these he felt confident that he should be able to
conquer the enemies of his country. Bolivar, after a variety
of prosperous adventures, was rapidly advancing towards
Caraccas, where the inhabitants waited for him, as their
deliverer. A junta was assembled, and it was proposed to
make proposals of capitulation to Bolivar. The general
accepted the offered treaty, and granted leave to any perfon,
who was defirous of it, to emigrate from Venezuela, and to
withdraw his property. The articles of the treaty, though
they were extremely liberal, were disapproved by the captain-
general Monteverde, because it was derogatory to the dig-
nity of the Spanish nation to treat with insurgents. Bolivar
made his triumphant entry into the city of Caraccas, amidst
the congratulations of the inhabitants, on the 4th of August,
1813. The dungeons of La Guayra were thrown open,
and those who had survived a year's confinement were re-
ferred to their country and friends; while the people,
shouting with joy, bleffed their deliverer, at the fight of
every individual who rushed from the prisons. In the midst
of this popular ferment, none of the Spaniards were in-
sulted. The provinces which formed the republic of Vene-
zuela were again in the power of the patriots; but Monte-
verde obstinately perfisted in refusing to treat with Bolivar.
In the mean while, Monteverde received from Spain a re-
forcement of about 1200 Spanish troops; and thinking
himself warranted to act offenfive, he attacked the repub-
licans, but was completely defeated. Almost all the Spaniards were killed or taken prisoners, and Monteverde
himself was severely wounded. After this defeat, Bolivar
laid siege to Puerto Cabello both by sea and land. But the
royalists retiring into the fortrefs, determined not to sur-
render. Bolivar, in invading Venezuela under the protec-
tion of the congress of New Grenada, had received orders
to reinfantine the republican congress; but this he did not
think it advisable to do. Bolivar, however, having given
an account of his intentions and operations, in the invasion
of Venezuela, to an assembly that had been convened of
persons of all ranks, resigned the supreme authority which
he held. But the governor of Caraccas proposed, and his
propofal was agreed to, that Bolivar, denominated the
"Libertador de Venezuela," should be invested with dicta-
torial authority, till the reunion of the provinces of Vene-
zuela to those of New Grenada, under the fame representa-
tive form of government. The Spaniards, not being able
to subdue Venezuela, determined to destroy it. Accord-
ingly the slaves were to be raifed in rebellion against their
masters. The number of slaves in Venezuela amounted to
70,000; and one of the most formidable emiJJarities for this
purpose was Boves, over whom Bolivar obtained a signal
victory at La Vitoria. After gaining several other con-
derable advantages over the royalists, Bolivar considered
himself as secure in the possession of Venezuela; and turned
his attention to Coro and Los Llanos, whither the enemy
had fled. But as the three divisions of the republican army
were separated many leagues from each other, Bolivar was
attacked by Boves on a plain called La Puerta nearly
50 leagues from Caraccas, and, after many hours fighting,
compelled to abandon the field to Boves. Other difafter
also occurred, and from this time confusion reigned among
the patriots, and there was no longer any army for the pro-
tection of Caraccas. Suets no longer attended Bolivar;
his former good fortune had forfaken him; and even the
commander of his flotilla, which protected the coast, refused
to obey his orders. Defparing of the independence of his
country, he and a few of his chofen officers, who were
willing to partake his ill fortune, embarked for Carthagena.
From Carthagena he proceeded to the town of Tunja,
where the congress of New Grenada was sitting; and he
was commissioned by the congress to compel by force the
city of Santa Fé de Bogota to acknowledge its authority.
In this he succeeded; after which he was sent with 3000
men
men to reduce to allegiance the province of Santa Marta. Carthagena was to contribute troops and guns; but it was prevailed upon to refuse the demanded supply, under pretext of Bolivar's ambitious views, and his faginary career in Venezuela. Bolivar marched against Carthagena; but intelligence having been received of the expedition from Spain having reached this city, Bolivar gave up his plan, quit the army, and his troops united to those of Carthagena to defend that city. The royalists entered Carthagena about four months after the siege had begun; but in the mean while, Bolivar, who had gone to Jamaica, proposed to affix Carthagena by landing an expedition on her shores. The capture of Carthagena prevented the execution of his plan, and he again turned his attention to Venezuela. Stimulated by the hopes of once flattering prospects, Bolivar planned an expedition for afflicting the efforts of the patriots of Margarreta; and joining Borion, an affluent native of Curacao, disembarked the emigrants from Venezuela, and part of the garrison which had evacuated Carthagena. Borion was appointed commander of the maritime forces, which were to be employed on this occasion. Sailing from Aux Cayes at the end of March, 1816, they landed in the beginning of May at La Margarita. From Margarita Bolivar failed for Carapabano, about five leagues west of the town of Cumana, of which he dispossessed the royalists; and having armed many of the corps of guerillas, who had advanced to join him, they failed for Ocumara. When he landed at Ocumara, he issued a proclamation, giving liberty to the slaves. This proclamation, dated July 6th, 1816, does honour to his judgment and feelings. "Your tyrants," says he, "shall be deposed and expelled, and you shall be restored to your rights, your country, and peace."—"No Spaniard shall be put to death, unless in battle. No American shall suffer the least injury for having joined the king's party, or for having committed acts of hostility against his fellow-citizens."—"That unhappy portion of our brethren, which has groaned under the miseries of slavery, is now set free. Nature, justice, and policy, demand the emancipation of the slaves; henceforward there shall be only one chiefs of people in Venezuela—all shall be citizens." Bolivar, who after the defeat at Ocumara had returned to Aux Cayes, brought new reinforcements to Margarita, where he landed in December, 1816. There he published a proclamation, convoking the representatives of Venezuela to a general congress; and went afterwards to Barcelona, where he organized a provisional government. In this place he repulsed the royalists under Real and Morales, in February or March, with great loss. Although the patriots lost the town of Barcelona on the 7th of April this year (1817), and the royalist forces in Venezuela received an addition of 1600 men from Spain in May last, it is now (Augufi) reported, that Bolivar has succeeded in completely establishing the republic of Venezuela. Travels in South America, by Depons, in 2 vols. 1807. Outline of the Revolution in Spanish America, by a South American, 1817.

VENEZUELA. See CORO.

VENGA-MIBOOR, a town of Hindooftan, in Myjore; 17 miles S.E. of Errood.

VENGA-PALEAM, a town of Hindooftan, in Myjore; 11 miles N.W. of Darzapour.

VENGO-LINA, in Ornithology, an African bird, which seems not to have been described by any of the ornithologists. According to the Hon. Daines Barrington's account, it is of the jucb tribe, and about the same size with our abbrev- daine, or flickin; the colours are grey and white, and the cock hath a bright yellow spot upon the rump; it is a very familiar bird, and sings better than any of those which are not European, except the American mocking-bird. Phil. Trans. vol. lxi. part ii. p. 254.

VENHYUSEN, in Geography, a town of Holland; 4 miles S.W. of Enckhuysen.

VENIA, among our Ancient Writers, denotes a kneeling, or low prostration, to the ground; used by penitents. See GENUFLEXION.

Wallingham, p. 156. "Rege interim prostrato in longa vena. Per venias, centum verrunt barbis pavimentum.""
of monks, twenty-six nunnaries, seventeen rich hospitalls, eighteen oratories, forty religious fraternities with their chapels, and fifty-three squares. The buildings, indeed, are all of stone; but the greater part mean, without beauty or elegance. St. Mark's square, it is true, is very fine, and so are the several stately marble palaces that border upon the grand canal, though most of them are of Gothic architecture. In the churches and convents, the most admirable parts are the paintings; and indeed Venice, highly renowned for fine paintings, is said, in this very respect, to have surpassed even Rome itself. Venice, from the fertility of its neighbourhood, and the facility of carriage, enjoys a constant plenty. The spring-water being very indifferent, almost every house has a cistern, into which the rain-water is conveyed from the roof, and clarified by being filtered through laid earth. Water is always brought from the Brenta, and preferred in cisterns. Among the diversions of Venice, the carnival is accounted the chief; it usually begins the second day of Christmas, and continues till Shrove-Tuesday; confifting chiefly of masquerades and ridottos: St. Mark's place is the general rendezvous. Other diversions are plays and operas. The trade in cloth, especially scarlet, silk goods, and looking-glasses, is still very considerable. Here also gold and silver fluffs are manufactured; which, although not so beautiful as those of France, have a very good sale in the Levant. The brocatellas, a kind of stuff like brocade, made of coarse silk, are much used for carpets. Venice is divided into six parts, called Selletiere di Selletiera. S. Marco contains the piazzetta of S. Marco, with the adjacent buildings. This square, the pride of the city, forms a right angle, the shortest side of which, two hundred and forty paces long, and seventy-five broad, reaches along the ducal palace. The ducal palace, towards the water-side and St. Mark's place, is entirely Gothic; but on the side of the small canal, and in the court, of modern architecture, and most finely wrought. It is arrived from the river Brenta, but also for the meeting of the council. The finest ornaments of the council-chamber and other apartments, are the paintings of ancient masters. In one side of the palace, towards the canal, Rio di palazzo, were dark prions, strongly secured with iron grates. The lower gallery, or arched walk, on the side of St. Mark's square, together with the opposite side, is called Broglio. Here, at a certain hour of the day, the nobles took their walks, and at this time the Venetian of an inferior rank must be seen on it; though a foreigner, as supposed unaccounted with the custom, is not desired to quit the place. Between these two buildings and the piazza were two pillars of Oriental granite, on one of which stood St. Mark's lion in brass, and on the other a marble statue of St. Theodore. Between these is the place for the public execution of malefactors, through which no nobleman is ever seen to pass. A gallery, completely rigged and armed, lay close to the Broglio, for the defence of the ducal palace on any sudden emergency. Contiguous to the north part of the doge's palace is St. Mark's church, also filled with the most stately paintings; but the church is entirely Gothic. The best part of it consists of the Mosaic paintings, and the four brass horseteers, formerly gilt, standing over the great door, and said to have been brought here from Constantiinople. In the church treasury is kept a very famous manuscript of the gospel of St. Mark, pretended to be autographical; but the dampness of the place where it lies has spoiled it to such a degree, that no part of it is any longer legible, and it is not so much as certain whether it be written in Latin or Greek. In the Selletiera di Caletello is the arsenal or dock, two Italian miles and a half in circuit, walled and moated in, with twelve towers along its walls; and within the inclosure a great variety of buildings, in which every thing requisite for a land or sea armament is kept in readiness; with shops, storehouses, and basons and slips for ship-building, &c. Within it lie the men of war, frigates, galleys, and other vessels, with the Bucentauro, which is also laid up here. In the Selletiera di Canale Regio is the theatre, and in this quarter the Jews live, to the amount of fifteen hundred, who must wear a flap of red cloth in their hats, by way of distinction from Christians. Selletiera di S. Pavolo contains the exchange, the bank, &c. On the invasion of Italy, in the fifth century, by the Huns, under their king Attila, and the general defolation that every where appeared, great numbers of the people who lived near the Adriatic took shelter in those islands where, in 1271, the city of Venice; and which islands, about the year 421, particularly Rialto, had, in some measure, been built upon by the Paduans, for the advantage of commerce. (See Venetia.) Here having settled their small places or fites, they were at first governed by consuls; afterwards by tribunes; and formed a kind of republic, the council of which was represtented by the persons of these magistrateaters. These islands became still better inhabited on the succeeding incursions of the Goths and Lombard into Italy; multitudes from Rome and other large cities repairing thither, so that this state became soon able to make some head against these bold invaders. At length the chiefs of the islands and the Longobardi came to an agreement, by which the former were to remain unmolested. This was the commencement of the city and state of Venice. About the beginning of the eighth, or end of the seventh century, the former government of these islands was abolished, and an unlimited power conferred on Paulicuo Aneafeto, with the title of duke. Under this sovereignty the state greatly increased, till the people, jolly becoming weary of the ills of domestic defpotism, in the year 1171, another duke, but curtailed his power, by asgining him a council of 240 persons, composed of commons as well as nobles. Duke Ziani sided with pope Alexander III. against the emperor Frederick, and obtained over him such a signall victory at sea, that the pope presented him with a ring, which he was to drop into the Adriatic, as a sign of his marriage with, and perpetual sovereignty over it. The Venetians, who had already extended their dominion into Istria, Dalmatia, Syria, Lombardy, and other places, made a very considerable acquisition in the beginning of the thirteenth century, by poiffessing themselves of the principal islands in the Archipelago and Mediterranean, particularly that of Candia. From this time they alone carried on, at an immense profit, the trade for East India goods, which they imported from Alexandria, in Egypt, to which place they were brought across the Red sea, and by the way of Suez. Under duke Marino Morosino was introduced the form of electing the doge; and it was at this juncture that jealousy and envy fomented the war with Genoa, which, after continuing 150 years, was at last put an end to by treaty, in 1281. During this war, duke Peter Grandonigo, in the year 1296, ordained that the nobility alone should be capable of sitting in the grand council. Thus the government became aristocratical. In the 14th century, the Venetians extended their possession in Lombardy; and, in 1473, the last king of Cyprus appointed the flate of Venice his heir. Towards the end of the 15th century, the Venetian commerce, and consequently power, began to decline, when the Portuguese discovered a route by sea to the East Indies, which opened the trade to all nations. In the 16th century, the pope, the emperor, France, and Spain, joining in a league against them, they were
were disembaffled of all their towns and places in the kingdom of Naples, the ecclesiastical state, and the Milanese. They received another severe blow from the Turks, who drove them out of the island of Cyprus. In the 17th century a sharp contest arose between the state, the clergy, and the pope, in which, however, they had the advantage. They were also long engaged in troublesome wars with the Turks, losing Candia, and gaining part of Dalmatia, and all Morea; but the greater part of these had been lost in preceding wars. Thus the republic of Venice continued upwards of 1300 years, amidst many foreign wars and intestine commotions. Its grandeur was chiefly owing to trade and liberty; and since the decline of the former, its strength and consequence must have suffered a considerable diminution. The power was lodged in the hands of the nobility, said to be near 2000, including those whom public employments in the provinces obliged to reside out of Venice.

On the birth of a nobleman's son, his name was entered in the golden book, otherwise he forfeited his nobility. Every noble was, indeed, a member of the senate; and on this account it was a received maxim, that they all were equal in dignity. But the difference, notwithstanding, between the interest and authority of families, was very considerable. To the first class belonged the ancient houses, whose ancestors had been to the duke, and who, from thence, were called "Le Cate Elettorali" and on them, preferably of all others, were conferred the higher offices. Next follow eight houses, almost as ancient. The second class had its origin from the Serar del Consiglio; duke Brandongio having passed a law that the council should perpetually confide of the families which then composed it, and some others which he enobled. This produced a second class of nobility, who, accordingly, were then registered in the golden book. It consisted of upwards of eighty families, and some of great wealth and reputation. With these were also included families raised to nobility after the Genoese war, on account of their large contributions towards carrying it on with vigour. The third and last class was composed of the Cittadini, or citizens, whose nobility was purchased for 100,000 Venetian ducats, a reissue of the republic for raising money in necessitous times. Crowned heads, German and other princes, have not thought it any degradation to be made nobles of Venice. The habit of the nobility, whill at Venice, was a black furred gown, reaching to their heels, with a belt about three inches broad, and plated with silver. Instead of hats they had long caps. The head of the republic was the doge, or duke, who, on the demise of the former, was chosen in a peculiar manner, by forty-one nobles, selected for this purpose by a process which it is needless to describe. These forty-one electors were confirmed by the grand council; and, being shut up in a chamber of the ducal palace, there remained till they had chosen a new doge. To the duke and legal election of a doge, it was required, that out of the forty-one he should have twenty-nine votes. His election was followed by a kind of coronation; the ducal cap being placed with great ceremony on his head. This was performed at his public entrance into St. Mark's church. His yearly income was 15,000 Venetian ducats. He was subject to a variety of solicitations; and he was under the inspection and control of the council of ten, who kept a watchful eye over his whole administration, and, at any time, could come and search his most private apartments. In general, his authority, essentially conferred, was no greater than that of a private person, unless he could influence the whole council. On his death a formal inquiry was made, whether he had abused his power; whether, from a care of his own concerns, he neglected thule of the public; whether he lived agreeably to his dignity, &c. If found guilty of any thing alleged to his charge, his heirs were fined in proportion to the nature of the crime. On Ascension-day, the doge, or, in case of illness, the vice-doge, performed the annual frivolous ceremony of marrying the Adriatic sea. (See Doges.) In the grand council, all nobles of the age of twenty-five years might take their place, though some younger found means to obtain admittance. The senate, or pregadi, were a committee of the grand council, by whom they were also chosen. This senate had the management of the most secret and important state affairs, as the making alliances and peace, declaring war, feeding embassadors, coinage money, filling up offices, imposing taxes, &c. Next was the collegium, in which all public instruments directed to the state and doge were read, audiences given to foreign ministers, and other matters of importance transacted. The procurators of St. Mark had not only the inspection of the church of St. Mark, its library, and the records of the republic, but likewise managed all affairs relating to the poor, together with wills, guardianships, redemption of Christian slaves, and bringing over rigid creditors to a reasonable composition. Their number never exceeded nine: their office was of great authority, and during life; and out of them the doge was generally chosen. Titular or extraordinary procurators of St. Mark were more numerous; the republic gladly filled these titles with a public fearcity of money. Il confiuggio di dieci was a high penal court, which consisted of ten counsellors, the doge, who was president, and his six confiliieri. The established religion was the Roman Catholic; but Greeks, Armenians, and Jews, were allowed the public exercise of their worship, and Protestants, observing privacy, remained un molested. The patriarch of Venice, the chief ecclesiastical of the republic, was chosen by the senate; and though confirmed by the pope, muft, in all other respects, be independent of the papal chair. The territories of the republic were under governors chosen out of the nobility, changed at the expiration of a certain term of years. The annual revenue of the republic was computed at 8,200,000 ducats, and was under the direction of three governors of the Entrate. In war-time, both the nobles and the other inhabitants, even the doge, were proportionably to their incomes, towards defraying the public expences. The flates of Italy subject to the Venetians were the Dogado, the Paduan, the Foligno di Roverigo, the Veronese, the Vicentin, the Bresan, the Bergamasco, the Cremasco, the Trevigiano, the Feltrino, the Bollone, the Cadorino, great part of Friuli, and Istria; to these may be added a part of Dalmatia, the islands of Corfu, Zante, Calabria, and some others. The number of inhabitants in the city of Venice was estimated at 100,000, and of the whole state, at 450,000. In the year 1797, in consequence of some partialities which the Venetians showed to Austria, the French attacked and made themselves masters of the city. By the peace of Luneville, Venice with its dominions was given to Austria; but by the peace of Preidburg transferred to the new kingdom of Italy. In December 1707, prince Eugene Napoleon was created prince of Venice by the emperor Napoleon.

Venice has always been renowned for its cultivation of the fine arts, and for giving birth to great professors, particularly in painting, architecture, and music. At the head of the first, Titian, Paul Veronese, and Tintoret; of the second, Palladio and Scamozzi; and of the third, Zanetti, Lotti, Marcello, and Galuppi; names that can never be heard without pleasure by the votaries of these arts. Printing, too, has been carried on at Venice with great spirit ever since the year 1459, when it was established there by Nicholaus
Nicholas Jansen; and in the beginning of the next century, purified by the Aldi with more accuracy than in any other part of Europe.

But Venice has long manifested its attachment to music by the establishment of its conservatories, or musical schools, of which it has four; the Opificio della Pietà, the Mendicanti, the Incorabile, and the Opisidalletto a S. Giovanni e Paolo; at each of which there is a performance every Saturday and Sunday evening, as well as on great festivals. The performers at them all, both vocal and instrumental, are females; the organs, violins, flutes, violoncellos, and even French horns and double-basses, are supplied by these females. See Conservatorio.

Though the composers of the Venetian school are, in general, good contrapuntists, yet their chief characteristics are delicacy of taste and fertility of invention; but many circumstances concur to render the music of Venice better, and more general, than elsewhere. The Venetians have few amusements but what the theatres afford; walking, riding, and all field-sports, are denied them. This in some degree accounts for music being so much, and in so costly a manner, cultivated; the number too of theatres, in all which the gondoliers have admission gratis, may account for the superior manner in which they sing, compared with people of the same clafs elsewhere. And in the private families, into which the girls of the conservatories marry, it is natural to suppose that good taste and a love for music are introduced.

Venice, in 1659, was the first city in Italy that opened public theatres for the performance of operas; and in less than a century from that period, 658 musical dramas were brought on the several stages of that city, the chief part of which were produced by natives of the Venetian state. In the last century, not only the poetry and music of the lyric theatre were greatly superior to those of preceding times, but the performers; for at Venice all the great vocal talents to which the opera had given birth, were more constantly summoned, patronised, and cherished, than in any other city of Europe.

Accounts are kept at Venice in lire of 20 foldi or mar- chetti; and each foldo is divided into 12 denari di lira. They are also kept in ducats of 24 grofi; and the grofio is divided into 12 grofiotti, or denari di ducato. A ducato of account is worth 63 lire, or 124 marchetti. The gold coins of the old republic are zecchini, or fequins, with halves and quarters. The fequins is commonly reckoned at 22 lire, but its agio fluctuates, and in the year 1805 it was 37 per cent. The silver coins are the fucdo Veneto, or della croce, of 12 lire 8 foldi, and halves and quarters in proportion; the ducatone, or giullina, of 11 lire; the ducato effettivo of 8 lire, with halves and quarters; and base silver pieces of 50 foldi, called laraze, and of 20, 15, 10, and 5 foldi. There are pieces of 10 lire, which were coined in 1796. The copper coins are foldi and half foldi, or bagattini.

When Venice became subject to Austria, in 1797, a base silver money was introduced, called moneta provinciale, which, in 1802, was declared to be out of currency; and a new coinage took place, confiting of pieces of 13 1/4, and 3/4 lira, or, in Austrian money, of 18, 12, and 6 centziners, which contained only a fourth of fine silver, but they were heavier than the former coinage. This money was called "moneta di nuovo flanco." The Austrian government also introduced copper pieces of 6 and 3 centziners, or 10 and 5 foldi, and pieces of 2 and 1 foldi. All the above-mentioned monies and coins are now valued in "moneta piccola," which is the effective currency of Venice.

The bank of Venice was instituted in 1587; its original capital being five millions of ducats. The owners received no interest for their money, but could draw it out on demand, or transfer it in payment, like the banks of Amsterdam, Hamburgh, and other banks of deposit. Bills of exchange were mostly paid in banco, and also wholesale bargains of merchandise above 300 ducats. The bank received no money but sequins and silver ducats. The bank of Venice was in high credit and prosperity from its first institution to the year 1797, when the French feized upon the city, and ceded it to Austria; from this period it declined. In 1805 Venice was incorporated with the kingdom of Italy; and in 1808, the bank was totally discontinued.

According to the rate of coinage at Venice, 684 sequins are equal to a Venetian mark of fine gold, with a very small, but uncertain, quantity of alloy. No remedy was allowed at the mint of Venice, either in the weight or fineness of its coins. The Venetian sequin, weighing nearly 1/24 English grains, is therefore worth 97 6d. sterl. The silver ducat weighs 351 1/2 English grains, and is 9 oz. 18 1/2 dwt. fine, which gives its value at 406d. sterl.; hence the ducat of account of 61 lire piccola is worth 31 1/2d. nearly, and the lira about 6d. sterl.; or, more exactly, 11l. sterl. = 47 lire 8 foldi piccoli. But taking the value of the lira from the coinage introduced by the Austrian government, it will be found worth about 43 1/4; and 1l. sterl. = 56 lire 9 3/4 foldi piccoli.

Venice has two different weights for merchandise, viz. pezo grofio, or large weight; and pezo fottile, or small weight: the pound of the former is divided into 12 oz. and 192 carats, in all 2.504 carats; and the pound of the latter into 12 oz. and 144 carats, in all 1728 carats. The pound pezo grofio weighs 19 oz. 0 pezo fottile; hence 12 lbs. pezo grofio = 19 lbs. pezo fottile; and 18 lbs. pezo grofio, or 28 1/2 pezo fottile = 19 lbs. avoirdupois. A carca is 400 lbs. pezo fottile. The ounce for weighing silk and thread is divided into fix laggri or fazi, and these into halves, quarters, &c. Oil is sold either by weight or measure: a migliao weight contains 40 min, each 25 lbs., in all 1000 lbs. pezo grofio. A migliao measure should contain 1210 lbs., or 40 min, each 30 1/2 lbs. pezo grofio: such a miro answers to about 4 1/2 English gallons. The amphora, a wine measure, contains 4 bigoncia; a bigoncia, 4 quartari, 16 fecchi, or 256 lbs. pezo grofio; but a bigoncia of brandy is only 14 fecchi.

Two forts of long measure are used at Venice, both of which are called the braccio; that for woollens is 26 English inches, and that for silks is 24 English inches. The Venetian foot is 154 French lines, or 13 English inches; hence 36 Venetian feet = 41 English feet.

Venice exchanges with London 50 lire piccola, more or less, for 1l. sterl.; at three months' date. The uaine for bills drawn from London is three months after date. Bills are allowed six days grace, after which they must be either paid or protested. Protests are made by the fanti or clerks of the commercial college, who enter all the bills they have protested in a book, to which every merchant has free access. Thus many bills, which would otherwise be returned, are accepted and paid for the honour of the drawer or indorser. This practice is likewise useful in giving early notice of approaching insolvency. (Kelly's Un. Camb.) Venice is situated 216 miles N. of Rome. N. lat. 45° 28'. E. long. 12° 18'.

VENICE, Gulf of. See Adriatic.

VENICIUM, in Ancient Geography, a town in the interior of the ifle of Corsica, according to Ptolem. VENICNIUM, a people who inhabited the western coaft of Hibernia. Ptol. VENICNIUM PROMONTORIUM, a promontory on the northern coaft of Hibernia. Ptol.

VENI-
VENICONTES, a people of Britain, S. of the Caledonii to the W. whose town was Orlea. Ptol.

VENIERO, DOMENICO, in Biography, an Italian poet, was born of a noble family at Venice in 1517: and after receiving a good education, and being introduced to the friendship of Bembo, and having been thus led into the way of advancement to honourable and lucrative stations, he fell the ufe of his limbs at the age of thirty-two, and was confined to his chamber for life. In this condition he fought solace from poetry and the conversation of his learned friends, who in great numbers returned to his house. These meetings laid the foundation of the celebrated Venetian academy, of which Veniero was the principal ornament. Notwithstanding the pain which he experienced, his poems are distinguished by liveliness of imagery and force of expression. He died in 1582, at the age of sixty-five. His poems were first printed in the collections of Dolce and Rucellii; and they were edited at Bergamo in 1751 and 1753, with those of his nephews, Maffeo and Luigi Veniero, the former of whom was archbishop of Corfu. Their father Lorenzo was also a poet. Gen. Biog.

VENIERE FACCAS, in Law, is a judicial writ, lying where two parties stand, and come to issue; directed to the sheriff, to cause twelve men, of the same neighbourhood, to meet to try the fame, and recognize the truth upon the issue taken.

Afterwards a compulsive process is awarded against the jurors, called bocas corpora juratam, or diligitas, that they may appear upon the day appointed. See Jury.

VENIERE FACCAS is also the name of a writ, which is the proper process in an indictment for any petty misdemeanor, or on a penal statute, and which is in the nature of a summons, to cause the party to appear. And if by the return to such venire it appears, that the party hath lands in the county by which he may be dilrated, then a diversus fquare shall be issued from time to time till he appears. But if the sheriff returns that he hath no lands in his bailiwick, then, upon his non-appearance, a writ of capias shall issue; and if he cannot be taken upon the writ capias, a second and a third still issue, called an alias, and a plures capias.

VENIERE FACCAS in Matrimon. See VENIERE INSEQUENTER.

VENISON, VEXATION, the flesh of beasts of game, or of animals to be caught in the way of game, i.e. by hunting, &c, as deer, hare, &c.

The word is French, venaison; formed of the Latin venatio, hunting.

The old hunters have determined, that every beast of the forest, that is food for man, is venison. In many parts of the world the bears are as regularly hunted as the hare and buck, &c. are with us, and are called venison; but with us, at present, the word venison seems limited to the flesh of the hart, the hind, the buck, the doe, and the other creatures of that kind.

Some have extended the signification of the word to the beasts of the forest which were chased as game, and afforded the diversion of hunting, whether their flesh were eaten or not; thus, in some places, the wolf and the fox are reckoned among the venison beasts.

VENIUS, or VAN-VENIUS, OTHO, in Biography, was of a distinguished family in Holland, and was born at Leyden in 1556. He received an excellent education from his parents, and though his progress in literature was uniform, yet he was permitted to pursue his desire of becoming a painter. He received lessons in design from Isaac Nicolas, but is more indebted to John Van Wagenen. The war in the Low Countries drove him to Liége at the age of fifteen, and there he continued to prosecute his studies in literature and the arts. He acquired the favour of cardinal Grofbeck, at that time prince bishop of Liége, who, desirous of his advancement, advised him to visit Rome, and furnished him with letters of recommendation to cardinal Marduccio, then in that city. On his arrival there he was kindly received and entertained by his eminence, and he became a disciple of Fred. Zuccharo, by whose instructions, and his own industry in studying the beautiful works of antiquity with which he was surrounded, he acquired a very great degree of correctness in design, and a more elevated taste than his countrymen usually exhibited in their works.

Having devoted seven years to his studies in Italy, he visited Germany, where he flaid some time, and received a flattering invitation to remain in the court of the emperor; but his desire to revisit his native country prevailed, and he declined this honourable proposal. As he passed through Münich and Cologne, he was employed by the duke of Bavaria and the elector; and on his arrival at Brufis, the governor, Alexander Farnefe, appointed him his principal engineer and painter, and faw to his portrait.

After the death of his patron he established himself at Antwerp, where he was much engaged in painting historical works for the churches, &c. and gained a great reputation, which has not been diminished by his having had for his disciple fo renowned an artist as Rubens.

When the archduke Albert was appointed governor of the Netherlands, Otho Venius made the designs for the triumphal arches erected on his entry, with which the archduke was so much gratified, that he invited him to Brufis, and appointed him his principal painter, and master of the mint, which situations he occupied till his death in 1634, at the age of 73.

Otho Venius did not confine himself to painting, he wrote and published several works adorned with prints, chiefly engraved by his brother, Gilbert Venius, from his designs. Among them are, a translation of part of Tacitus; Horace's Emblems, with notes and observations; the Life of Thomas Aquinas; and the Emblems of Love, divine and profane.

VENIZY, in Geography, a town of France, in the department of the Yonne; 3 miles N. of St. Florentin.

VENLO, a town of France, in the department of the Lower Meuffe, late the duchy of Guelderdon, situated on the E. side of the Meuffe, takes its name from the two Flemish words Vien and Lex, which signify a low meadow. Before the year 1343, it was only a small town, when René 11. duke of Guelders, fortified it, and gave it the title and privileges of a city. It has only one parish church, which is dedicated to St. John. After several changes of possessors, it was ceded, in 1715, to the States-General by the barrier treaty. In this town was made the first trial of bombs, about 1588; and they were first used by Alexander Farnefe, duke of Parma, at the siege of Watchendoon, not long after. In 1754, it was taken by the French; 12 miles N.N.E. of Roermond. N. lat. 51° 27'. E. long. 6° 24'.

VENNO, a town of the republic of Lucca; 5 miles S.S.W. of Lucca.

VENO, a small Danish island, in the gulf of Lymencid. N. lat. 56° 14'; E. long. 8° 58'.

VENOM, VENISON. See Poison.

The terms venem and venen only differ from each other in this, that the latter is more frequently used where the noxious matter is taken internally, as in foods, drinks, &c., and the former, where it is applied externally, as in the bite of serpents, &c. 

The pike is said to have a venenous tooth. All manner of beasts, in the general, have that quality in greater or less.
when bred in mountains and dry places, than when in wet and marshy places; and the southern more than the northern; those hungry and enraged, more than others; and all of them in summer more than winter. See Viper.

VENONIS, in Ancient Geography, a town of Britain, in the 9th Iter of Antonine, situated between Ratis or Leicester, at the distance of 12 miles from it, and Bannaventum near Daventry; supposed to be the present Cleycester.

VENOSA, CARLO Gesualdo, Prince of; in Biography, a Neapolitan nobleman, whose fame has been extended by his musical productions more than by his high rank, though this rank will be found reciprocally to have added lustre to the compositions, was nephew to cardinal Alfonso Gesualdo, archbishop of Naples, and had his title from the place which gave birth to Horace, the Venafium of the ancients. Pomponius Nenna, a voluminous and celebrated composer of madrigals, had the honour to instruct him in music. His productions consist of six fets of madrigals for five voices, and one for six. The principal editor of his works was Simone Molinaro, maefro di capella at Genoa, who, in 1581, published the fifth five books in separate parts; and, in 1613, the fame madrigals, with the addition of a sixth book, in score.

The numerous editions of these madrigals in different parts of Europe, and the eulogies bestowed on the author by persons who rank high in literature, as well as in music, made us extremely curious to see and examine them. Gerard Vofius, Biaconoii, Bapt. Doni, Taffoni, and many others, speak of him as the greatest composer of modern times; as one who, quitting the beaten track of other musicians, had discovered new melodies, new measures, new harmonies, and new modulation; so that fingers, and players on instruments, defpising all other music, were only pleased with that of this prince.

Taffoni tells us, that James I. king of Scotland, had not only composed sacred music, but invented a new species of plaintive melody, different from all others; "in which he has been imitated by the prince of Venosa, who, in our times, has embellished music with many admirable inventions."

This passage in Taffoni, which has so often been cited by Scots writers, seems to imply, not only that James, king of Scotland, had invented a new species of melody, but that his melody had been imitated by the prince of Venosa; at least, this is the sense in which the passage has been understood by the natives of Scotland, and indeed by ourselves, till, on finding no kind of similarity between the national tunes of North Britain and the melodies of the prince of Venosa, we examined the passage anew, with more attention; when it appeared to us as if Taffoni's words did not imply that the prince of Venosa had adopted or imitated the melodies of king James; but that these princely dilettanti were equally cultivators and inventors of music. See David Rizzio, Scots Tunes, and Ossian.

The Neapolitan prince seems to merit as little praise on account of the expressiof of words, for which he has been celebrated by Doni, as for his counterpoint; for the syllables are constantly made long or short, just as it belt suited his melody; and in the repetition of words, we frequently see the same syllable long in one bar, and short in another, or the contrary; by which it is manifest that their just accentuation was never thought of.

The remarks of Taffoni certainly must have been hazarded either from conjecture or report; as is but too frequently practised by men of letters, when they become musical critics, without either industry or science sufficient to verify their assertions.

The prince of Venosa was perpetually straining at new expression and modulation, but seldom succeeded to the satisfaction of critics, however dazzled his contemporaries may have been by his rank, and the character he bore among the learned, who so frequently get their musical information from tradition, that whether they praise or censure, it is usually sans connoissance de cause.

Dilettanti usually decide in the fame summary way, with an additional prejudice in favour of their own little knowledge, and a disposition to censure whatever they are unable to acquire, be it science or execution.

Cicero has long since said, that "it is not with philosophy and science, as with other arts; for what can a man say of geometry or music, who has never studied them? He must either hold his tongue, or talk nonsense."

With respect to the excellencies which have been so liberally bestowed on this author, who died in 1614, they are all disputable, and such as, by a careful examination of his works, he seems by no means entitled to. They have lately been said to consist in "fine contrivance, original harmony, and the free modulations conceivable." As to contrivance, it must be owned that much has been attempted by this prince; but he is far from being happy in this particular, that his points of imitation are generally unmanageable, and brought in so indiscriminately on conords and discords, and on accented and unaccented parts of a bar, that, when performed, there is more confusion in the general effect than in the music of any other composer of madrigals with whose works we are acquainted.

His original harmony, after scoring a great part of his madrigals, particularly those that have been the most celebrated, is difficult to discover; for had there been any warrantable combinations of sounds that Palestrina, Luca Marenzio, and many of his predecessors, had not used before him, in figuring the bajes, they would have appeared. And as to his modulation, it is so far from being the free modulations conceivable, that, to us, it seems forced, affected, and disgusting.

We have bestowed more remarks on this prince of musicians, and more time in the examination of his works, than perhaps they now deserve, in order to furnish our readers with what seems to our comprehension, a truer idea of their worth, than that which partiality and ignorance have hitherto given. A score of one of his madrigals in the 3d vol. of Burney's Gen. Hist. of Mus. p. 223, will justify our censure of the musical productions of this tuneful prince.

VENOSA, in Geography, a town of Naples, in Basilicata, the see of a bishop, sufragans of Matera. It contains seven churches, and as many convents. In the 9th century, Venosa was taken by the Saracens, and in 1528 by the French; 9 miles N.N.W. of Acerenza. N. lat. 40° 58'. E. long. 15° 45'.

VENOSA Arteria. See Arteria Venosa.

VENOSTA, in Geography, a valley of the Tyrol, on the banks of the Adige; 20 miles S. of Glurnretz.

VENOSUM Foliim, in Botany and Vegetable Physiology, a very leaf. See LEAF and VEN.

VENOUS, VENOSUS. See VENAL.

VENT, in Geography, a river of England, in the county of Cumberland, which runs into the South Tyne.

VENT, formed from ventus, wind, vent-hole, or spireak, a little aperture left in the tubes or pipes of fountains, to facilitate the air's escape; or, on occasion, to give them air; as in frothy weather, &c. for want of which they are apt to burst.

A vent, taken in this fenfe, is properly the end of a pipe, placed
placed erect, and reaching above the ground; usually foled to the turns, or elbows, of pipes. The vents of large pipes are to be as high as the superfcie of the refervoir, unless there be a valve in them.

Vent is also used for a little hole, pierced in vessels of wine, beer, &c. that are on tap; and which admits air enough to make the liquor run, but not so much as to corrupt and spoil it.

Vent, again, is applied to the covers in wind-furnaces, by which the air enters, which serves them for bellows; and which are flopped with regillers, or slices, according to the degree of heat required; as in the furnaces of glafs-houses, alayers, &c.

Vent is also used for a pipe of lead, or other matter; one end of which opens into the cell of a necessafy-houfe, and the other reaches to the roof of the houfe, to give room for the corrupt feid air to exhale.

There are also vents, or apertures, made in the walls which fulfil terraces, to furnish air, and give a paffage for the waters.

This kind of vent the Italians, and we from them, call a barbacane.

Vent, in Gunnerly. See Touch-Hole.

The common method of placing the vent is within about a quarter of an inch from the bottom of the chamber or bore. Some, however, have thought, that if the vent was to come out at the middle of the charge, the powder would be inflamed in less time than in any other cafe; but Mr. Muller, by firing mortars with two vents, one at the bottom and the other in the middle, and fo contrived that one was flutt whilf the other served to fire, found always the range of the shell greater when the lower vent was used, than when the powder was fired by the middle one. Artillery, p. 83.

Mr. Thompson (Count Rumford) has lately made a number of experiments, in order to determine the best position of the vent; from the refult of which it appears, that the effect of placing the vent in different positions with respect to the bottom of the chamber, is different in different charges; but the difference in the force exerted by the powder, which arose from the particular position of the vent, was in all cafes fo inconsiderable, as to afford occasion for concluding, that any given charge of powder exerts nearly the fame force, whatever is the position of the vent. He infers, upon the whole, that in the formation of fire-arms no regard need be had to any suppofted advantages that gunsmiths and others have propofed to derive from particular situations for the vent; such as diminifhing the recoil, increafing the force of the charge, &c.; but the vent may be indifferentiy in any part of the chamber where it will help answer upon other accounts; and he thinks there is little doubt but the fame thing will hold good in great guns, and all kinds of heavy artillery. Workmen in general agree, that the vent in fire-arms should be as low or far back as poiffible, in order, as they conceive, to felfen the recoil: accordingly fome make the bottom of the chamber flat, and bring the vent out even with the end of the breech-pin; others make the vent flanting through the breech-pin, in fuch a manner as to enter the bore juft in its axis; others again make the bottom of the chamber conical; and there are fhoes who make a little cyfindrical cavity in the breech-pin, of about two-tents of an inch in diameter, and near half an inch in length, coinciding with the axis of the bore, and bring out the vent even with the bottom of this little cavity.

The objection to the firt method is, that the vent is apt to be flopped up by the foul matter that adheres to the

Vol. XXXVI.
VEN

VENTA Sierra, mountains of South America, in the province of Venezuela.

VENTALDA, a town of Sweden, in the province of Smaland; 34 miles S.E. of Jonköping.

VENTAROLI, a name given in Sicily, &c. to groottes formed under their houfes, from which itfues a conflant extreeme cold wind, and at times with impetuoufity, and a noife like water dafhing upon rocks. Thefe are that up with doors like cellars, and made ufe of as fuch, as alfo to keep provifions freth, and to cool liquors. At Cefi, in the Roman ftate, there are many fuch ventaroli; and the inha-bitants of that town, by means of leaden pipes, conduct the freh air from thefe into the rooms of their houfes, fo that by turning a cock they can cool them to any degree. Some who have refined fhh more upon this ufed, by smaller pipes, bring cold air under the dining table, fo as to cool the bottle of liquor upon it. On mount Aetna and Vefuvius, and in the ifland of Sicily, there are many caverns of this kind. Phil. Trans. vol. lxx. part i. p. 73.

VENTENATIA, in Botany, was fo named by M. Paliflot-Beauvois, in honour of the late M. E. P. Ventenat, member of the National Institute, a diftinguifhed French botanift, who was formerly an eccleifiastic, and, if we miftake not, of fome religious order; but he took advantage of the revolution to free himfelf from fuch unnatural and immoral fhafticles, in order to fulfil the duties of a man and a C'riflian. He has diftinguifhed himfelf by the publication of a Tableau du Regne Vegetal, fuii la Methode de Jufhieu, in 4 vols. 8vo.; as well as the magnificent Jardin de la Malmaison, with coloured plates, in large folio; and the uncoloured Jardin de Cels, and Chois de Plantes; the latter having been foon cut short by his death. The writer of this article had dedicated to the name of M. Ventenat, a New Holland genus, (fee Stylidium,) which now yields to the prior right that the genus before us.—Pail. Beauv. Fl. d'Oware et de Benin, falc. 2. De Theis 479. Poiret in Lamarck Dict. v. 8. 450. — C'iffs and order, Polyandra Monogynia. Nat. Ord. Tiliaceae Juf.?

Gen. Ch. Cal. Perianth inferior, in three deep, equal, oblong, obtufe, concave, coriaceous, deciduous segments. Cor. Petals numerous (eleven or twelve), spatulate, fpreading, fhongly vifcous ; rounded at the extremity; contracted into a claw at the base. Stam. Filaments numerous, thread-shaped, crefh, unequal, much shorter than the petals, enters, like them, into the receptacle; anthers . . . . .

Pil. Germanus superior, oval; ftyle thread-shaped, un divided, longer than the flaments; stigma thick, obfequrely five-lobed. Peric. Berry oval-oblong, of five cells, furrowed longitudinally, terminating in a kind of mammillary point. Sedic numerous in each cell.

Eff. Ch. Petals numerous. Calyx in three deep deciduous segments. Berry superior, of five cells, with many feeds.

Obfs. M. Paliflot Beauvois remarks, that this genus is obviously referrible to Jufhieu's 13th clafs, (Poiret by miitake fays the 34,) but its order in that clafs is not fo easily determined. Difficulties of the ripe feed are wanting to afcertain this point. The fruit nearly accord with Jufhieu's Aurantia, but the flrucre of the flower, and the want of pellicid dots in the leaves, exclude it from that order. The want of fipulas prevents its perfect agreement with the Tiliaceae, and M. Beauvois confiders this genus as probably making one of a new order, confounded by Jufhieu with his Tiliaceae.

1. V. glauca. Glaucus Ventenatia. Palif. Beauv. Fl. d'Oware et de Benin, 29. t. 17. Poir. n. 1. — Native of elevated, airy, open situations, near Agathon, on the coast of Africa. A furb, with alternate, round, smooth branches. Leaves alternate, falked, very large, elliptic-oblong, entire, tipped with a long acute point; rounded at the base; smooth on both fides; covered on the under furface with a kind of glaucous viscidity, which when dry becomes almoft powdery. Sipulas none. Flowers lateral, towards the extremity of each branch, solitary, falked, alternate, sometimes opposite to the leaves; their fials half the length of the leaves, cylindrical. Calyx short, smooth. Corolla large, of a fine crinfon, beautifully vifcous. Poiret.

VENTER, in Anatomy, the abdomen; called alfo minus venter. See Abdome.

Venter is alfo ufed for the womb, or uterus, of women. And hence the writ de ventre infipidus.

Hence, alfo, in the civil law, we fay, partus sequitur ventrem, the child follows the belly; meaning, that its condition is either free or fervile, according to that of its mother.

They alfo fay, to appoint a curator for the belly, with regard to pollhumous children, yet in the mother's womb. With regard to princes, the venter, or belly, has been fometimes crowned in form.

Venter is alfo ufed, in speaking of a partition of the effects of a father and mother, among children born, or accruing, from different marriages.

This partition is fo ordered, that as a fingle child of one marriage, or venter, takes as much as several of another marriage, or venter; in order to which, the estate is divided into fo many parts as there have been venters, or marriages.

Venter, or Belly, of a fuckle. See Belly of a Mufkle.

VENTER Dractus, Dragon's Belly, in Astronomy. See Dragon's Belly. See alfo DRACON, in Astronomy.

Venter Equi, Horse's Belly, among Chemifls, denotes horfe-dung, or a dunghill, on which are inclosed certain vessels for particular operations, to be perfoved by means of the gentle heat of it.

VENÊTES la Grandes, in Geography, a town of France, in the department of the Lower Seine; 9 miles N.W. of Neufchâtel.

VENTHIE, La, a town of France, in the department of the Straits of Calais; 9 miles N.E. of Bethune.

VENTIA, in Ancient Geography, or Venfjtium Civitas, a town fuated in the Maritime Alps. Dion Caffius, speaking of an expedition, dated in the year of Rome 693, against the Allobroges, who had revolted, mentions a town under this name, at a small diftance from the Ifer. According to some circumstances pertaining to this expedition, there is reafon to believe that it is Venei, between Moirène, or Tuilin and St. Marcellin, at some diftance from the right bank of the Ifer.

VENTIDUCTS, in Building, are spiracles, or subterraneous places, where freh cool winds, being kept, are made to communicate by means of tubes, funnels, or vaults, with the chambers, or other apartments of a house, to cool them in sultry weather.

There are much in use in Italy, where they are called ventidotti. Among the French they are denominated prifons de vents, and palais d'Eole. See VENTAROLI.

VENTILAGO, in Botany, so called by Gartnner, because the appendage to the feed-veil was thought to bear some refeonance to a winnow or flapper, ventilabrum. It does not answer to the common idea of a fan, being neither plaiated, nor much dilated upwards.—Gart. v. 1. 223. t. 49. Wild. Sp. Pl. v. 1. 1106. Roxb. Coromand. v. 1. 55. Mart. Mill. Dict. v. 4. Poiret in Lamarck Dict. v. 8. 452. — Clafs

Gen. Ch. Cal. Perianth inferior, of one leaf, cup-shaped, with five equal, triangular, deciduous, marginal segments. Cor. Petals five, flatulate, inserted into the rim of the calyx, alternate with its segments, and rather longer. Stam. Filaments five, awl-shaped, opposite to the petals, the length of the calyx; anthers of two round lobes. Petal. Germ. superior, inserted below with the tube of the calyx, nearly globose; style short, cloven half way down; stigmas two, divaricata, acute. Peric. Capsule globalus, of one cell, and two valves; splitting at the base; crowned at the summit with an elliptic-oblong, flat, coriaceous, ribbed wing, many times longer than the capsule. Seed solitary, globose.

Eff. Ch. Calyx cup-shaped, with five deciduous segments. Petals five, opposite to the flaments. Capsule of one cell, crowned by an elongated wing. Seed solitary.

Obl. Gaertner did not see the capule in a sufficiently advanced state to discover that it has really two valves, which separate at the base, continuing connected at the apex by their long coriaceous wing, in which the most remarkable character of the genus consists. The flowers are occasionally dioecious, from the imperfection of one or other organ of impregnation.

1. V. madorepatana. Yerra Chiraltay of the Telingas. Willd. n. 1. Roxb. Coromand. v. i. 35. t. 75. (Fucus viminalis; Rumph. Amboin. v. 5. 3. t. 2.)—Native of forests and uncultivated places, among the mountains of Hindoostan and Ceylon, and of rocky thickness on the shores of Ambonya, flowering in the cold season. The stem is woody, climbing to a great extent, with long, round, pliant, tough, leafy, often downy, branches. Leaves alternate, on short flabell, ovate, blunter, two or three inches long, coriaceous, more or less obscurely crenate, feldom quite entire, smooth or minutely downy, furnished with one midrib, and many transverse ones, connected by extremely fine parallel veins. Flowers very numerous, small, greenish-white, in large, terminal, compound panicles, their scent highly offensive, resembling Sterculia fasida. Wing of the calyx entire, greenish-yellow, slightly downy, above an inch in length.—Willdenow, according to Poiret, has distinguished two species of this genus, in the new Transactions of the Berlin Society; one having entire and smooth, the other crenate and downy, leaves. But we are persuaded, from an examination of wild specimens from Roxburgh and Koenig, that these characters are variable.

VENTILATION OF Mines, comprises the various modes by which impure air is removed, and a current of atmospheric air propelled through the subterranean openings and passages of mines. The health, the safety, and lives of a very large and industrious class of the community depend on the regular ventilation of mines; yet the application of the principles on which this should be undertaken has been but imperfectly understood, and it is but very recently that the subject has engaged the attention of men of science. Since the constitution of the atmosphere was ascertained, (see ATMOSPHERE,) it is well known that the one-fifth part of it, or the oxygen gas, is essentially necessary to support the processes of respiration or combustion, by which it undergoes a chemical change, and is converted into carbonic acid gas, a gas destructive of animal life, and in which flame is instantly extinguished. It is also well known, that the remaining four parts of the atmosphere, or the azote, are equally destructive of life, and incapable of supporting flame; hence the necessity of ventilation, or a regular supply of fresh air, in all confined situations, where men are to labour or exist, is very easily explained. Besides the destruction of oxygen gas by respiration or combustion, which takes place in confined apartments above ground, there are other causes that render the air impure in almost all subterranean passages or mines, through which there is not a regular current of wind constantly passing. The causes by which the air in mines is rendered impure, or destructive of animal life, are of three kinds. First, the respiration of men and horses in the mine, and the combustion of the lamps, &c.; secondly, the production and evolution of carbonic acid gas in the beds or strata in which the mine is situated; and thirdly, the production of carburetted hydrogen or inflammable gas. For the properties of these gases, see Gas. The two former sources of impurity are much less destructive of life than the latter, the inflammable gas or fire-damp of the miners: when this becomes mixed to a certain degree with the air of the mine, it explodes with great violence on the approach of a lamp or candle, and occasions the most fatal accidents, destroying all the vital air in the mine, and burning or suffocating the workmen. By explosions of this nature, it was estimated that not less than five hundred persons perished during the years 1814 and 1815, in the coal-mines on the rivers Tyne and Wear, in Northumberland and Durham; and the destruction of human life in other coal districts has been necessarily equally great, in proportion to their extent. In the ventilation of mines, where the air is impure from respiration, combustion, or the evolution of carbonic acid gas, called by the miners choak-damp, the object of the miner is simply to introduce a current of fresh air; through the workings; but besides the difficulties to be overcome in effecting this, where the works are extensive, the miner who has to combat with the fire-damp must guard against the greatest evil of an explosion, to which he is almost constantly exposed.

In the working of metallic mines, the veins being generally nearly vertical, the currents of water, or the natural passages, aided by the varied temperature of the mine, are frequently sufficient to infuse the circulation of air; and these mines are very rarely affected by the production of the fire or choak damp. It is principally where a shaft or well is sunk, or a horizontal passage or gallery is made, that any means of artificial ventilation are necessary. The most obvious remedy, and that which is most frequently resorted to, is opening a communication with some other part of the mine, or with the surface; and when this is done, the ventilation is found to be perfect by the rushing of the currents, which often takes place with considerable force, from the different degrees of temperature in the lower and upper air, and these currents change their direction as the temperatures above and below alternate. The great objection to this mode is the expense with which it is commonly attended wherever the gallery is at a great depth, and the intervening rock of a very hard kind, and where a shaft is merely wanted to supply air, and not for the passage of the water. To avoid this, the shaft or level is sometimes divided into two distinct parts, communicating near the part intended to be ventilated, so that a current may be produced in opposite directions on each side of the partition; and this is often effectual to a certain extent. It has, however, its limits at no very great distance, and the current is but a feeble one, from the nearly equal temperature of the air on each side of the partition.

The other mode employed is to force air down tubes with a large pair of bellows worked by the hand, or by boxes or cylinders of various forms placed on the surface, with a large opening against the wind, and a smaller one communicating with the air-pipes by a cylinder and piston.
work in it, and when driven by a sufficient force, this has
great power. Mr. John Taylor, in the Transactions of the Society of
Arts for 1810, has described a method of effecting this process
more easily, by attaching an air-pump of a very simple con-
struction to a small fall of water. The engine discharges
more than two hundred gallons of air in a minute, and a
stream of water supplied by an inch and a half bore falling
twelve feet is sufficient to keep it regularly working. This
method may be introduced with great advantage into narrow
passages or wells, but would be obviously inadequate to
ventilate the immense excavations in coal-mines. Except it
were confined to some confined part of the works. In
metalliferous mines, the generation of the fire-damp is much
less frequent than in coal-mines, and the extent and position of
the excavations make the ventilation of the latter a
labour of much greater difficulty. The most valuable beds of
coal in England, with the exception of Staffordshire, are
from two to nine feet in thickness, and they rarely incline
more than about fifteen or twenty degrees from the horizon-
tal level, and are frequently nearly flat. Each pit has two
shafts or wells, called the downcast pit and the upcast pit.
The excavations or passages in the coal, which communicate
from one pit to the other, are frequently not less than forty
miles or more in length, through which circuitous route the
air has to take its course, though the distance from the
downcast to the upcast shaft, in a right line, may not be
more than a few hundred yards or feet, or even much nearer.
And here we cannot but observe, that as the means to force
the air through a route of such extent must be very com-
plicated, and as a failure or accident to a part might de-
stroy the whole ventilation, we conceive that much too large
a surface is frequently worked from two shafts, in order to
avoid the expense of additional shafts for several detached
workings of a smaller extent. By this, the risk of the
workmen is greatly increased, to save expence to the
owners of the coal. In the year 1813, some gentlemen in the
north of England, impressed by the dreadful catastro-
phes which had recently taken place, very laudably esta-
lished a society, with a view to inquire into the causes of
these calamities, and the possible means of prevention.
They entitled themselves "A Society for preventing Acci-
idents in Coal-Mines." Mr. John Buddle, an eminent coal-
viewer in Northumberland, addressed a letter to the prefi-
dent, which was published by the society in 1815. In this
letter he details the various methods which had been em-
ployed for the prevention of accidents by fire, which, he
says, "conflict in a mechanical application of the atmo-
spheric air to the removal or sweeping away of the inflam-
mable gas, as it is generated in the workings of collieries, or
as it issues from the fissures which the workings intersect in
their progress." He details the various methods by which
this is effected: these are explained by a number of figures
and sections, without which they could not be rendered in-
telligible to the reader. We shall endeavour to give an idea
of the principle on which the various modes of ventilating
mines depend, by stating one of the simplest forms in which
they can act. If two wells or shafts were sunk at a given
distance, five yards from each other, and a horizontal
passage were cut from the bottom of one well to the other,
so soon as the communication were made, there would be a
tendency in the air to defend one shaft and ascend the other,
whenever the temperature of the external air varied from
that of the air below. The currents of air in natural cavities,
that are open at each extremity, proceed from the
same cause. In certain latitudes of the atmosphere, should the
current not be sufficient, or should a quantity of impure air
be generated in the passage, the circulation may be increased
by kindling a fire at the top or at the bottom of one of the
wells, to rarefy the air and cause it to ascend more rapidly.
Or the air may be forced down the other well, by causing a
stream of water to fall into it. Also by means of vanes, or
by an air-pump attached to a steam-engine, the circulation
may be easily increased according to the will of the engi-
neer, and the facilities which may be preferred for carrying
away the water, &c. Thus little difficulty could arise in a
cache of simple ventilation of this kind; but if from the hori-
izontal passage which runs from one shaft to the other, we
pass to a number of passages on each side at right angles with
it, as is the case in the current of air which passes
through it will not enter these lateral passageways, or occasion
any circulation in them. In order, therefore, to make the
air pass through the whole series, another passage must be
opened, connecting the further extremities of the lateral
passageways with each other; the first passage must then be
closed, and the air which descends continued along the
lateral passageways, up one and down the other, taking a cir-
cuitous route through the whole, until it arrives at the up-
cast shaft, which it ascends. To conduct the air in this
manner, a number of trap-doors and flaps are necessary, in
order to prevent the mixture of the air from the different
passageways, which would entirely destroy the ventilation. See
Plate IV. Geology, fig. 8, which represents part of the
workings of a coal-mine; the shaded part is the bed of
coal, in which the workings are carried along the different
passageways, from the pit or shaft a, to the pit or shaft b.
The current of air is represented by darts and dotted lines.
The flaps and trap-doors, which close to prevent the passage
of the air, and confine the currents to a particular course,
are represented by double lines and cross lines, as at &. This
figure represents the improved system of ventilation,
by which the current of air sweeps every part of the work-
ings. By tracing the darts and dotted lines, it will be seen
that the current of air from the downcast pit a, first passes
along the main passage to A, and the adjoining passage
M B, to which it has access through lateral passageways, called
wells, 1, 2, 3, 4: its further progress in every direction is
closed, except at 5, where it enters the passage C, from
which it has access to the passage D, through the openings
6, 7, 8, 9: at E, the currents unite in one stream, and enter
an advanced part of the workings, called the head-ways, ven-
tilating the passageways F and G, being forced into them by
partitions called braclets, placed at X X, round which the
air must pass in its progress to H.
Where the current of air divides and sweeps along two
passageways at the same time, and unites again as above-
described, it is called double couring; but where it runs
down one passage and up another, as may be seen in its
further progress from H on the south side, to H on the north
side of the mine, it is called single couring.
The remaining part of the ventilation back to the passageway
K, is in double couring, along which it is forced by the
flapings at 1, 2, 3, and the other flapings 4, 5, 6, until
it ascends the upcast shaft at b. Under this system, says
Mr. Buddle, if the flapings, &c. be all in order, and the
passages kept sufficiently open for the current of air to circu-
late freely, there can be no partial stagnations in the work-
ings,—no accumulation of inflammable gas. For in the event
of a large discharge of gas, from what is called a blower,
commencing at any place, as at M, N, P, Q, its fire is
immediately carried off by the circulating current of atmo-
spheric air, and so diluted that it cannot explode, unless
indeed the discharge of inflammable air should be so copious
as to mix with the current up to the firing point, or to that
degree
VENTILATION.

degree in which it would inflame by access to a lighted candle or to fire.

This improved system of ventilation by double courses was introduced into the collieries on the Tyne and Wear about the year 1760, and has ever since continued in general use; but it is found inadequate to the intended purpose in the following cases:

1. When sudden discharges of inflammable gas mix with and raise the whole circulating mafs of air to the firing point.
2. When the wind is south-eaft, and the weather wet or lamy, and the barometer sinks below twenty-nine inches.

In this cafe the atmoferic current, which under the most favourable state of the air is merely sufficient to fweep the noxious effuflia from some mines, gets fo contaminated by the discharge of inflammable gas, and the fławness of its own progres, as to be exceedingly unsafe, and generally inacceffible with candles.

3. When inflammable air fills a part of the mine between the workmen and the upcast shaft.
4. When the gas is ignited by lightning, as it afcends the upcast shaft.

The preffence of inflammable gas from the lighted mixture, through all its gradations to the firft firing point, is readily difcoverable by an experienced collier, and he judges very correctly of the degree of inflammabillty and danger which threaten the safety of the mine, by obferving attentively the appearance of the fire upon the top of his candle. The common pit-candles vary in fize, but thofe generally used are forty-five to the pound; the wick is of cotton, and the candle made of ox or sheep tallow: but clean ox-tallow is best.

The mode of trying the candle, as it is called, to ascerfain the mixture of inflammable gas, is as follows:

In the firft place, the liquid fat is wiped off, the wick faufed clofe, and carefully cleaned of red embers, fo that the flames may burn as purely as pooffible. The candle, being thus prepared, is held between the fingers and thumb of the one hand, and the palm of the other is placed between the eye of the obferver and the flame, fo that nothing but the fire and the flame can be feen, as it gradually fovers over the upper margin of the hand. The obfervation is generally commenced near the floor of the mine, and the light and hand are gently raifed up, till the true flate of the circulating current be ascerfain.

The firft indication of the preffence of inflammable air is a light ting of blue or a blue-fky colour shooting up from the top of the fire to the candle, and terminating in a fine extended point. The fire increafes in fize, and receives a deeper ting of blue as it rises through an increafed proportion of inflammable gas, till it reaches the firft point; but the experienced collier knows accurately enough all the gradations of fhow (as it is called) upon the candle, and is very rarely fired upon, excepting in fudden discharges of inflammable gas. The fhow upon the top of the candle varies very much, according to the length of run or diftance which the current of air has paffed through before it is mixed with the inflammable gas. The shorter the run of the current of air before it is mixed with the inflammable gas, the fhow will be the fhow upon the candle when at the firft firing point, and vice versâ.

The fame fize of fhow which would indicate danger in a current which had paffed only one mile, might be perfectly harmless in a current that had run five or fix miles; confequently the length of run of the current of air is to be taken into confideration, as well as the appearance of the top of the candle. The air-courses, too, for a short diftance beyond a small fhow or discharge of fire-damp may be highly inflammable; but by paffing a few yards further, it becomes fo diluted as to be perfectly secure. The diftance, therefore, within which a blower can be fafely approached with candles, is regulated entirely by the magnitude of the discharge and power of the current of air. Long eperience and careful obfervation are confequently necelfary to obtain a thorough practical knowledge of this art.

The workings of a colliery are very often inacceffible with candles near the downcast pit, called the firft of the air, while they may be fafely entered with any description of light near the upcast pit, called the fift of the air. This arises from the inflammable gas, as it is carried from the place of its discharge, being gradually diluted by the atmoferic current. Hence the advantage of fufficient extent of pit-room, to obtain length of run to dilute the inflammable air. It is from the want of pit-room, that the explosions in newly-opened collieries are generally the moft violent. The diftance which the current of air paffes through, between the downcast and the upcast pits, varies much according to circumftances. Mr. Biddle has known it to exceed thirty miles.

After the current of atmoferic air is fo highly mixed with inflammable air as not to be inacceffible with lighted candles, fteel-mills may be employed with safety. We fhall further notice Mr. Biddle's obfervations on fteel-mills, but we believe the discovery of the safety-lamp will entirely fupercede their ufe. "Although the inflammable air has frequently fired at the fpars of the fteel-mills, it only happens, from all the facts which I have been able to collect, when the mills are played near the place where the hydrogen gas is difcharged, and this by due attention may be eafily avoided.

"I never indeed witneffed an explosion from the fpars of fteel; but from my own obfervations on their appearance in dangerous fates of the air, as well as from the obfervations of several intelligent men, I believe that in many cafes the change of the appearance of the fpars, if attentively obferved, gives fufficient notice of the threatening danger. When elicited in atmoferic air, they are of a bright appearance, rather inclining to a redbit hue, and as they fly from the wheel feem sharp and pointed. In a current of air mixed with inflammable gas above the firing point with candles, they increafe conliderably in fize and become more luminous. On approaching the firing point with fteel-mills, they grow still more luminous, and assume a fort of liquid appearance, nearly resembing the fpars arifing under the hammer from iron at the welding heat. They also adhere more than usual to the periphery of the wheel, encompassing it as it were with a dream of fire, and the light emanating from them is of a bluflit tint. When the inflammable gas predominates in the circulating current, the fpars from the fteel-mill are of a blood-red colour; and as the mixture increafes, the mill totally ceafes to elicite fpars. They have the fame bloody colour in carbolic acid." The fteel-mill here mentioned is what has been ufed till very recently in coal-mines, consisting of a wheel and spring, which is wound up and let in motion, when by a conftant collision of flint and fteel it is elicited, eliciting a copious flream of fpars.

With the concluding remarks of Mr. Biddle's letter we can by no means agree, when he adds, "On the strength of my own experience in collieries thus circumfcribed, I freely hazard my opinion, that any further application of mechanical agency towards preventing explosion in coal-mines would be ineffectual." Among the means enumerated by this gentleman, the very obvious one of depending on the greater specific levity of the carbonifed hydrogen gas is entirely omitted;
omitted; nor is it even stated, that the general inclination of the air to prevent facilities for the ascent of the inflammable air, were requisite precautions taken to conduct it by channels to the mouth of the uptake pit, which in many situations might be done at a trifling expense.

The public have been given to understand, that an improved and complete system of ventilation, depending on this principle, had been introduced into some of the Staffordshire collieries; but on recent inquiry at the place, we were informed, that the method of ventilation proposed by Mr. Ryan had never been carried into practice to the full extent stated, but considerable advantage had been derived from a partial application of the principle, by making channels near the roof of the mine for the escape of the inflammable gas.

Where the air rises regularly for a considerable extent, unbroken by faults, it appears easy to discharge the inflammable gas as fast as it is generated. The specific gravity of carburetted hydrogen is little more than one-half the weight of atmospheric air, being as .555 to 1000. If, therefore, it were conducted along the roof by an unobstructed passage to the uptake shaft, it would rise and discharge itself.

Explosions not unfrequently take place at the uptake shaft, from the inflammable air passing near the fire placed at the bottom to rarify the air and increase the circulation. The only expedient at present suggested is the use of charcoal, as the gas will not ignite at a red heat without flame; but charcoal does not promote so rapid a circulation of air as coal or wood, which produce smoke and flame. The carbonic acid gas generated by the combustion of charcoal, being also heavier than atmospheric air, would, in some degree, retard the ascent of air from the uptake shaft; and if a small particle of coal fell upon the charcoal fire, it would produce flame, which might cause an explosion.

A series of most interesting experiments was undertaken by Sir H. Davy in 1815, on the degree of inflammability of different mixtures of carburetted hydrogen when passed through small tubes or apertures, which led to the very important and unexpected result, that carburetted hydrogen, mixed with atmospheric air in the proportion which is most explosive, and then ignited, will not set fire to another portion of the same air, separated from it by a sieve of small wire, the meshes of which amount to two hundred and fifty in the square inch. On this principle he constructed a lamp surrounded by a small wire-ribe in the place of horn or glass, having no aperture for the admission or recombination of air but through the meshes of the sieve. This lamp, when lighted, was found to burn in explosive mixtures with perfect safety, the flame being confined within the lamp by the intervening wire-ribe. This lamp has since undergone considerable improvements, and some of the objections to which it was first exposed have been removed. Important additions to it are still making by its illustrious inventor.

For a full account of its construction and recent improvements, we must refer to the article Wire-Gauze Safety-Lamp.

VENTILATOR, a machine by which thenoxious air of any close place, as an hospitall, gaol, ship, chamber, &c. may be discharged and changed for fresh.

The noxious qualities of bad air have been long known; and no one has taken greater pains to fet the mischief arising from foul air in a just light than Dr. Hales; who has also proposed an easy and effectual remedy by the use of his ventilators; his account of which was read to the Royal Society in May, 1741. In the November following, Mr. Trievald, military architect to the king of Sweden, informed Dr. Mortimer, secretary to the Royal Society, that he had in the preceding spring invented a machine for the use of his majesty's men of war, in order to draw out the bad air from under their decks, the leaf of which exhausted 36,172 cubic feet of air in an hour, or at the rate of 21,732 tons in twenty-four hours. In 1742 he sent one of them, formed for a sixty-gun ship, to France; which was approved of by the Royal Academy of Sciences at Paris; and the king of France ordered all the men of war to be furnished with the like ventilators.

The ventilators invented by Dr. Hales consist of a square box, A B C D (Plate XVII. Pneumatics, fig. 1.) of any size; in the middle of one side of this box a broad partition, or midriff, is fixed by hinges X, and it moves up and down, from A to C, by means of an iron rod Z R, fixed at a proper distance from the other end of the midriff, and paffing through a small hole in the cover of the box up to R. Two boxes of this kind may be employed at once, and the two iron rods may be fixed to a lever F G (fig. 2.) moving on a fixed centre O; so that by the alternate raising and pressing down of the lever F G, the midriffs are also alternately raised and depressed, by which these double bellows are at the same time both drawing in air, and pouring it out through apertures with valves made on the same side with, and placed both above and below the hinges of the midriffs. In order to render the midriffs light, they are made of four bars lengthwise, and as many across them breadthwise, the vacant spaces being filled up with thin pannels of fir-board; and that they may move to and fro with the greater ease, and without touching the sides of the boxes, there is an iron regulator fixed upright to the middle of the end of the box A C (fig. 1.) from N to L, with a notch cut into the middle of the end of the midriff at Z, so that the midriffs, in rising and falling, suffer no other friction than what is made between the regulator and the notch. Moreover, as the midriff Z X moves with its edges only one-twentieth of an inch from the sides of the box A B C D E F, very little air will escape by the edges, and, therefore, there will be no need of leathern sides, as in the common bellows. The end of the box at A C is made a little circular, that it may be better adapted between A and C to the rising and falling midriff; and at the other end, X, of the midriff, a slip of leather may be nailed over the joints, if needful. The eight large valves, through which the air is to pass, are placed at the hinge-end of the boxes B K (fig. 2.) as at 1, 2, 3, &c. The valve 1 opens inward to admit the air to enter, when the midriff is depressed at the other end, by means of the lever F G. And at the same time the valve 3 in the lower ventilator is shut by the compressed air which passes out at the valve 4. But when that midriff is raised, the valve 1 shuts, and the air passes out at the valve 2. And it is the same with the valves 5, 6, &c. of the other box; so that the midriffs are alternately rising and falling, and two of the ventilators drawing in air, and two blowing it out; the air entering at the valves 1, 3, 6, 8, and passing out at the valves 2, 4, 5, 7. Before these last valves there is fixed to the ventilator a box Q N M (fig. 3.), as a common receptacle for all the air which comes out of these valves; which air passes off by the trunk P, through the wall of a building.

For a farther account of this machine we refer to the author himself, who gives a full detail of it, and of its manner of working. See Description of Ventilators, by Stephen Hales, D.D. Lond. 1743, 8vo.

The doctor has shewn the use of his ventilators very fully. As to ships, in particular, he observes, that the wind-fail, (see Wind-Sail,) made use of at sea to introduce fresh air between
between decks, is far from being sufficient for that purpose; nor can it be used with equal safety to the sick, and those who are sleeping, by means of the strength of the wind, which conveys the air with too much violence. But when the foul air is carried off by means of ventilators, notwithstanding the great velocity with which they throw out the air, which they may do at the rate of sixty tons in a minute, yet the motion of it downwards into the hold, to supply what was carried off, is so very gentle that it cannot be perceived; because the sum of all the open passages for it through the deck exceeds the opening of the trunk of the ventilator, in so great a proportion as 100 to 1, or more. Besides, in a calm, the wind-fail can do little or no good; nor when the ship is under fail, at which time the wind-fail is not used. And it is to be observed, that it is not the ventilating of a ship now and then with a wind-fail, when wind and weather serve, that will suffice; it ought to be done daily, if due regard be had to the health of the ship's crew. The great quantity of rancid noxious vapours, which are incessantly exhalating from a number of living human bodies, the stench that incessantly arises from the bilge-water, and from the hot, flagrant, putrid air in the hold, makes it very advisable to refresh so bad an air continually, either with the wind-fail, when that can be properly used, or else with ventilators, which are intended to supply the defects of the wind-fail.

Ventilators must also be of particular service in new ships, which are observed to be more unhealthy, on account of a greater quantity of sappy wreck which arises from new timber, and makes the confined air the more unwholesome. They will also be an effectual preservative of horses in transports, where they are sometimes suffocated, when in a storm there is a necessity to shut the hatches down.

These ventilators will also drive out of the hold of a ship that dangerous vapour which arises from corn, which is so noxious, that sometimes they dare not venture into the hold, till after the hatches have been opened for some time.

Ventilation will not only be of service to preserve several kinds of goods, but also the timbers and planks of the hold itself; when laid up in ordinary, as well as when in use, and will make the air in the hold less noxious, though it will still be offensive to the smell, by reason of the bilge-water. But this may be made less offensive, by often letting in sweet water from the sea, and then pumping it out; which good practice ought to be continued, notwithstanding the use of the ventilators.

What is here said of the foul air of ships may be applied to that of mines, gaols, workhouses, barracks, and hospitals. In mines, ventilators may guard against the suffocations, and other terrible accidents arising from damp; which fee. (See also Ventilation.) The air of gaols has been often known to be infectious; and we had a fatal proof of this, by the accident that happened some years ago at the fissions at the Old Bailey. To guard against the like for the future, as well as to preserve the health of the prisoners, a worthy magistrate, in 1752, had ventilators placed in Newgate, which were wrought by a windmill; and in the beginning of the year 1753, Dr. Hales gave an account of the good effects attending the use of these machines, by a remarkable decrease in the usual mortality and sickness of that place. Although the old prison at Newgate is now taken down, and a much more commodious one erected near the same spot, it may not be improper to give a brief account of the manner in which the ventilators of Dr. Hales were contrived, and how they were moved by the windmill annexed to them. The midriffs, b, b, (fig. 4) of these two ventilators, two pairs of which were laid upon one another, were each nine feet long, and four and a half wide, and moved up and down by the flat iron rods, e, e, passing through the lower and upper ventilators, and through an iron plate at s, about three inches square; over which is another broader iron plate, with a wide hole in its middle, to give room for the iron rod at g to move sideways to and fro, with the under plate, the hole of which exactly fits the iron rod, so that no air can escape at g; and there are the like plates at i, the top of the ventilator; and at f, g, are joints, where the iron rods are fixed to the midriffs, by which means both are moved up and down at the same time; and the iron rods of both sides of the ventilators being fixed to one common lever at r, e, all the four midriffs are thereby alternately worked up and down at the same time. The valve-holes v, v, x, x, &c. are twenty-three inches long, and six and a half wide, covered with buckram glued on them, and move on lifts of tanned sheepskin, and fall on lifts of woolen cloth nailed round the valve-holes. A very large nofe (fig. 5.) is fixed with iron hooks k, k, to the ventilators l, l; and this nofe is divided into three spaces, the middle and largest of which, m m, receives all the foul air blown into it from the eight middle valves x, x, x, x, (fig. 4.), whence it passed through a trunk t, t, sixteen inches wide, through the leads of the prision, into the open air, the top of this trunk being covered with weatherboards to keep the rain out, and the middle valves hanging so as to open outward. The two other outer spaces of the nofe p, p, receive the foul air, drawn into them, from the several wards, through the trunk s, s, and passing off into the ventilators, through the eight outer valve-holes v, v, v, v, whose valves open inward. In these outer partitions of the nofe there are two holes z, z, (fig. 5.) covered with boxes, in the bottom of each of which there is a large moveable valve, opening upwards, and towards the ventilators; these are made of such a weight, as to open only when all the trunks to the several wards are shut: by which the ventilators will always be supplied with air, so as not to endanger the breaking of the midriffs for want of it.

These ventilators, about eighteen inches deep in the clear, were fixed in an upper room of Newgate, in order to be near the windmill on the leads, which worked them. From each of the outer midriffs there went a trunk, twelve inches in the clear within, and from these trunks, which descended through all the floors as far as a little below the ceiling of the ground rooms, lesser trunks, six inches square, within, branched off, near the ceiling of every room; and extended more or less into the several wards, so that when the foul air was drawn out of any ward, the fresh air might enter on the opposite side, and drive out all the foul air before it. By other contrivances with sliding shutters and handles, the several wards might be ventilated at such a time, or in such a degree, as was found necessary. In the case of a prison that is built with an open area in the middle, Dr. Hales observes, that the side of the prison which is opposite to the side where the ventilators are, may be comminually ventilated in its turn, by having a round brick air-gutter under ground; through which the foul air of those wards might easily be drawn.

The windmill for working the ventilators was contrived to move with a small degree of wind, and to obtain a sufficient power in a small compass. In fig. 6., is one of the cross-tees which support the mill-pole, and the braces, c, c, the
the cross-trees reat on the blocks $a$, $a$, and are fixed to the floor by strong iron bolts. The mill-pole $d$, being hollow, and the head or base $b$ being passed through from the crank of the iron axle-tree $i$; the turning-frame $g$ moves on the girdele $f$, on which lies a broad circular iron plate, where is the bearing of the brafs friction-wheels, whose iron axle-trees move in brafs collars: the turning-frame $g$ carries the axle-tree $i$, and the fails $k$, which are turned, so as always to face the wind, by the vane $b$; the frame is kept from wrack- ing by iron braces $g$, $r$, represented by the double pricked lines. The crank $x$ is six inches and a half long, and therefore gives a stroke of thirteen inches; but the lower end of the rod $x$ is fixed to the lever of the ventilator (fig. 4) at such a distance from the centre of its motion, as to raise and fall the middriff fifteen inches. The iron axle-tree extends forward, about two feet and a half beyond the face of the fails; from the extremity of which, $z$ eight iron braces, $l$, go to each arm, to which they are fastened by iron screw-bolts, which bind them and the iron circle of pricked lines $m$ (fig. 7) fall together: the diameter of this circle is six feet, and the sarms or arms of the mill $k$ are seven feet three inches long, and they are mortised into the drum $y$. A void space of about fix inches breadth is left between the fails, as represented in the figures, that the direct current of the wind, as it passed through, might give a turn to the course of the wind; which otherwise, being driven obliquely from the face of the preceding fail, would be forced to act on the back of the following fail, and thereby abate the force, and retard the motion of the mill. The brake-pole (fig. 6.) is $n$; and the single pricked line $t$ at the end of it is the sword which is to clasp round the nave to fl op the mill, by pulling the rope $w$: $o$ is the bottom shear-tree of the turning-frame; and $p$ expresses the manner of screwing the brafs collars of the axle-tree nearer and nearer, as they wear away. For a farther account of this machine, see Hales's Treatise of Ventilators, part ii. 1758, p. 32, &c.

Dr. Hales farther suggests, that ventilators might be of ufe in making falt, in order to which there should be a fream of water to work them, or they might be worked by a windmill, and the brine fhould be in long narrow canals, covered with boards or canvas, about a foot above the surface of the brine, in order to confine the fream of air, fo as to make it act upon the surface of the brine, and carry off the water in vapours. Thus it might be reduced to a dry falt, with a faving of fuel, in winter and fummer, or in a rainy or dry flate of the air. Ventilators, he apprehends, might also ferve for drying linen hung in low, long, narrow galleries, efpecially in damp, rainy weather, and also in drying woolen cloths, after they are full’d or dyed, and in this cafe they might be worked by the fulling water-mill. Ventilators might also be an ufeful appendage to malt and hop-kilns; in which cafe it would be beft to have the air-trunk enter the kiln about eighteen or twenty-four inches from the ground, and juft opposite to the fire; but in order to prevent the air's blowing too strongly on the fire, a feam of brick-work might be formed about a yard distant from the hole of the air-trunk, and a yard square; for thus the air from the ventilators would be better diffufed through the whole kiln.

Dr. Hales is alfo of opinion, that a ventilation of warm dry air from the adjoining flove, with a cautious hand, might be of ufe to trees and plants in greenhouses; where it is well known that an air full of the rancid vapours, which perifh from the plants, is very unkindly to them, as well as the vapours from human bodies are to men. For freh air is as neccfary to the healthy flate of vegetables as of animals.

The larger kinds of ventilators ufed by the doctor, are ten feet long, five feet broad, and two feet high in the clear within. Thole he ufed by way of experiment on board the Captain, a seventy-gun ship, were ten feet long, four feet three inches wide in the clear within, and thirteen inches deep; one inch of which being occupied by the middriff, there remained a foot depth for it to rise and fall in. A ventilator of these dimensions will, through a trunk of a foot square, drive the air at the rate of twenty-five miles in an hour, which is double of what Mariotte affigns for the velocity of a pretty strong wind.

But besides these large ventilators, the doctor made a smaller falt, four feet in length, fixteen inches in breadth, and thirteen inches deep, all in the clear within. This smaller ventilator may be very ufeful in preferring the bread, in the bread-room of a ship, fweet and dry. Peafe alfo, and oatmeal, which are apt to heat and fpoil in cafsks, may be preferred, by putting them into a large bin, with a falf bottom of hair-clath laid on bars, by which freh air may be blown upwards through them with thefe small ventilators.

Ventilators are alfo of excellent ufe for the drying of corn, hop, and malt. See Granary.

Gunpowder may be thoroughly dried, by blowing air up through it by means of ventilators. What advantage dry gunpowder has over that which is damp, may be fecn by the experiment mentioned in the article Gunpowder.

Thofe small ventilators will alfo ferve to purify moft easily and efl'ectually the bad air of a ship's well, when there is occafion for perfon's to go down into it, by blowing air through a trunk, reaching within a yard of the bottom of the well, both for fome time before, and during their flay there. They may alfo be made ufe of at fea to fweeten flinking water, &c. See Sea-Water.

Dr. Hales made alfo feveral trials for curing ill-tafled milk by ventilation.

For thefe and other ufc's to which they might be applied, as well as for a particular account of the confttruction and disposition of ventilators in fhips, hospitals, prisons, &c. and the benefits attending them, see Hales's Treatise on Ventilators, part ii. paffim; and Phil. Tranf. vol. xii. p. 322, &c.

The ventilators in large ships, since the order for ventilating the fleet, iffued by the lords of the Admiralty in 1756, are fixed in the gunner's fore-floore-room, and generally a-head of the faii-room. The foul air is carried up through the decks and fore-calle, near the fore-maft, {sometimes afore it, and {ometimes abait it, but more frequently on its {barboard {ide; the lever, by which the ventilators are worked, is under the fore-calle in two-deck {hips, and be{teen the upper and middle decks in three-deckers; sometimes the lever is hung athwart-ships; in some {hips afore and aft; and in others oblique. The iron rod, which communicates the motion from the lever, passes through the partners of the fore-maft, and is connected with another lever, i{pended at or near the middle; in some {hips {over the ventilators; in others under them, when it is found nece{fary to fix them up to the deck. The bell method to fave room is to place the ventilators over one another, with their {ircular ends together; the air-trunk {hould be fo high above deck, that the men on deck may not be incommo{ded by the foul air which {blows out of it; and therefore the trunk comes through the upper deck, near and behind the
the fore-mast. Dr. Hales has calculated the following table
for the sizes of ventilators, &c. adapted to ships of war.

The construction of twenty-gun ships being various, the sizes of ventilators for these must be left to the direction of the officers of the yard.

When the hold is to be ventilated from one end to the other, the three doors of the gang-way into the gunner's floor-room must be opened, and all the gratings on the gun-deck be covered with tarpaulins, leaving all doors open, whose rooms want ventilation, on the orlop and the forecastle-room hatch. But when it is thought proper to ventilate between decks, then the doors of the gang-way into the gunner's floor-room must be shut, and the scuttle in the headmost trunk or pipe upon the gun-deck must be opened; and all the gratings of the middle deck, if the ship be a three-decker, or of the upper deck, if it be a two-deck ship, be laid with tarpaulins; and, if possible, one of the aftermost opened, or the aftermost hatch-way, or a scuttle on purpose, through the deck, as near the stern as possible.

Hales's Treat. part ii. p. 97, &c.

The method of drawing off air from ships by means of fire-pipes, whichsome have preferred to ventilators, was published by Sir Robert Moray in the Phil. Trans. for 1665. These are mettalline pipes, about two inches and a half in diameter, one of which reaches from the fire-place to the well of the ship; the other three branches go to other parts of the ship; the hole-hole and ah-hole being cloed up, the fire is supplied with air through these pipes. The defects of these, compared with ventilators, are especially examined by Dr. Hales, ubi supra, p. 113. See Air-Pipe and Ship.

Mr. Eranmus King proposed to have ventilators worked by the fire-engines in mines; and Mr. Fitzgerald has suggested an improved method of doing this, which he has also illustrated by figures. See Phil. Trans. vol. l. p. 727, &c.

There are various ways of ventilating the air of rooms. Mr. Tidd contrived to admit fresh air into a room, by taking out the middle upper sash-pane of glasses, and fixing in its place a frame-box, with a round hole in its middle, about six or seven inches diameter; in which hole are fixed, behind each other, two or three small twirling windmills, with fans of very thin broad copper-plates, which spread over and cover the circular hole, so as to make the air which enters the room to spread round in thin sheets sideways; and thus not to inconvenience persons, by blowing directly upon them, as it would do if it were not hindered by the fans, which turn on the same axle-tree, each lea from the other.

This method of refreshing rooms is much approved of, and used by many, not only in England, but also in other countries. For other methods of ventilating ships, build-ings, rooms, &c. see Air-Chamber, Bellows, Air-Pipe, Centrifugal Wheel, and Wind-Sail. Vol. XXXVI.

VENTILLA, in Geography, a town of Peru, in the diocese of La Paz; 9 miles S. of La Paz.

VENTININA, a term used by Paracelsus and his followers, to express the art of divining, or knowing by the winds and their courses the good or ill effects of seances.

VENTIS Pontes, in Ancient Geography, a town of Hispania, in Betica, in the vicinity of Carthago.

VENTO, MATTEO, in Biography, a Neapolitan, and disciple of Jomelli. That, however, is not discoverable in his compositions, which are easy and graceful, but have none of the solidity or originality of his master. Arriving in England in 1764, at the inauspicious termination of the reign of the Mingotti and Giardini, at the Opera, he had the good fortune to be engag'd by Gordon and Vincent, the new impresarios, to compose an opera, in which Manzoli was to perform the principal part. The opera which he had to fet was the Demofoonte of Metastasio, of which the airs are natural, graceful, and pleasing; all free from vulgar-ity, but never new or learned. They were, however, in great public and private favour a considerable time. In 1765, on the second arrival of Ehi. he fet Sophonisba, in that easy and graceful style which pleased more generally than what professors would call better music. This drama was repeated more frequently than any other during the seison, and the songs, printed by the elder Wilkie, were long after in favour at concerts and public places, as well as among piping milks and dilettanti.

In 1767, on the arrival of Guarducci, Vento set the opera of "La Conquilla del Mellico," of which the airs, like those of his former operas, were elegant and pleasing. After this he seems to have filled up his whole time in teaching, till the arrival of Gabrieli, in 1776, when he set "La Veilale," in his usual easy style; and when we told him that his airs were somewhat too familiar for the stage, he said, "God forbid I should ever compose difficult music!"

This composer's harpsichord pieces are light and fluid, yet above all things he is a master of the fiddle. There are few in the world who can strike the notes so well as he with the bow, that's why he is not only a master of the fiddle, but also a master of the violin.

VENTO, Matteo, in Biography. See Biagi, Pietro. VENTOSITY, in Medicine. See Flatulence and Tympanites.
VENTOSO, Cape, in Geography, a cape on the N.E. coast of the island of Cabrera, in the Mediterranean. N. lat. 39° 10'. E. long. 2° 53'.

VENTOTIENA, in Geography, an island in the Mediterranean, near the coast of Naples, anciently called Pandataris; according to Dr. William Hamilton, composed of volcanic matter thrown up by fire. It is now, as it seems to have been for ages, used as a place of banishment for criminals of a superior rank. Hither Julia, the daughter of Augustus, was sent, accompanied by her mother Scribonia. Some years the virtuous Agrrippina was also confined here; and Octavia, wife of Nero, and daughter of Claudius, was at the indulgence of Poppea banished and murdered in this island; 17 miles W. of Hitha. N. lat. 40° 53'. E. long. 13° 19'.

VENTURÉ, in Ancient Geography, a town of Italy; to which the Romans sent a colony about the year 331 from the foundation of Rome, according to Diodorus Siculus.

VENTURÉ, in Geography, a town of Hindoostan, in the circuit of Ellore; 7 miles W. of Ellore.

VENTUS Insigniens, in Law, a writ for the search of a widow that she is with child, and thereby holds land from him that is, otherwise, next heir at law. See Jury of Masters.

VENTREVRE, in Geography, a small island in the Atlantic, near the coast of France. N. lat. 47° 28'. W. long. 2° 59'.

VENTRICULUS, in Anatomy, the stomach. See Stomach.

Ventriculi Cordis, the two cavities of the heart, which propel the blood into the arteries; they are the right and left, or pulmonary and aortic. See Heart.

Ventriculi or Ventricles of the Brain, cavities in different parts of its substance. They are the two lateral, right and left, called also tricomes; the 3d, 4th, and 5th, or ventricile of the septum lucidum. See Brain.

Ventriculi Arbor. See Arbor.

Ventriculus Saccentiaritus, in Medicine, a name given by some to the duodenum, when very large. Med. Ef. Edinb. abr. vol. ii. p. 34.

VENTRILLOQUUS, Ventriloquus, compounded of venter, belly, and loquor, I speak, gastrophoia, or engastrimythus, a term applied to persons who speak inwardly; having a peculiar art of forming speech, by drawing the air into the lungs; so that the voice, proceeding out of the thorax, to a voluntary and articulated forms to come from some distance, or in any direction. See Engastrimythus.

Such a person we had formerly in London, a smith by profession, who had the faculty in such perfection, that he could make his voice appear, now, as if it came out of the cellar; and the next minute, as if in an upper room; and nobody present could perceive that he spoke at all. Accordingly, he has frequently called a person first up, then down stairs; then out of doors, then this way, then that, and all this without stirring from his seat, or appearing to speak at all.

We cannot forbear making a few extracts on this curious subject, from a work, published in 1772, entitled "Le Ventriloque," &c. or the Ventriloquy, by M. de la Chapelle, cenór royal at Paris, member of the Academies of Lyons and Rouen, and F.R.S. Some faint traces of the art or faculty of ventriloquism are to be found in the writings of the ancients; but many more are to be discovered there, if we adopt this author's opinion, that the responses of many of the ancient oracles were actually delivered by persons professing this quality, so very capable of being applied to the purport of priestcraft and delusion. The abbé de la Chapelle, having heard many surprising circumstances related concerning one M. St. Gille, a grocer at St. Germain-en-Laye, near Paris, whose powers as a ventriloquist had given occasion to many singular and diverting scenes, formed the resolution of seeing him. Being seated with him on the opposite side of a fire in a parlour on the ground-floor, and very anxiously observing him, the abbé, after half an hour's conversation with M. St. Gille, heard himself called, on a sudden, by his name and title, in a voice that seemed to come from the 10th of a house at a distance; and whilst he was pointing to the house from which the voice had appeared to him to proceed, he was yet more surprised by hearing the words: "It was not from that quarter," apparently in the same kind of voice as before, but which now seemed to issue from under the earth, at one of the corners of the room. In short, this facetious voice played, as it were, every where about him, and seemed to proceed from any quarter, or distance, from which the operator chose to transmit it to him. To the abbé, though conscious that the voice proceeded from the mouth of M. St. Gille, he appeared absolutely mute, while he was exercising this talent; nor could any change in his countenance be discovered. He observed, however, that M. St. Gille prefented only the profile of his face to him, while he was speaking as a ventriloquist. On another occasion, M. St. Gille sought for shelter from a storm in a neighbouring convenent, and finding the community in mourning, and enquiring the cause, he was told, that one of their body much cherished by them had lately died. Some of the religious attended him to the church, and shewing him the tomb of their deceased brother, spoke very feelingly of the bounty honours that had been bestowed on his memory; when suddenly a voice was heard, apparently proceeding from the roof of the choir, lamenting the situation of the defunct in purgatory, and reproaching the brethren with their want of zeal on his account. The whole community being afterwards convened into the church, the voice from the roof renewed its lamentations and reproaches, and the whole convent fell on their faces, and vowed a solemn reparation. Accordingly they first chanted a de profundis in full choir, during the intervals of which the ghoul occasionally expressed the comfort he received from their pious exercises and ejaculations in his behalf. The prior, when this religious service was concluded, entered into a serious conversation with M. St. Gille, and inveighed against the absurd incredulity of our modern sceptics, and pretended philosophers, on the article of ghouls and apparitions; and M. St. Gille found it difficult to convince the fathers that the whole was a judicious deception.

Another instance of his extraordinary powers occurred in presence of a large party, confining of commissaries from the Royal Academy of Sciences at Paris, and other person of the highest quality, together with a certain lady, who was not in the secret, and who was only told, that an aerial spirit had lately established itself in the forest of St. Germain-en-Laye, and that they were assembled to inquire into the reality of the fact. When the party sat down to dinner, the aerial spirit began to address the lady with a voice that seemed to be in the air over their heads; sometimes he spoke to her from the trees around them, or from the surface of the ground at a great distance; and at other times from a considerable depth under her feet. The lady, being thus addressed for more than two hours, was firmly persuaded that this was the voice of an aerial spirit; and it was some time before she was undeceived.

Several other instances of M. St. Gille's talents are related; and the abbé, in the course of his inquiries, was

Informed.
formed, that the baron de Mengen, a German nobleman, possessed this art in a very high degree. He also relates, from Brodeuc, a learned critic in the sixteenth century, one of the singular feats performed by a capital ventriloquist in his time, who was called Louis Brabant, and was valet de chambre to Francis I. Our countryman Dickson speaks of him particularly, in his tract entitled "Delphi Pheniciantes," printed in duodecimo at Oxford, in 1655. Louis had fallen in love with a beautiful and rich heiress, but was rejected by the parents as an unfit match, on account of his low circumstances. However, the father dying, he wifheds to be the widower; and on his first appearance in the house, he hears herself accused in a voice resembling that of her dead husband, and which seemed to proceed from above. "Give my daughter in marriage to Louis Brabant, who is a man of great fortune, and excellent character; I now endure the inexpiable torments of purgatory, for having refused her to him; obey this admonition, and I shall be soon delivered; you will provide a worthy husband for your daughter, and procure everlasting repose to the soul of your poor husband." The dread summons, which had no appearance of proceeding from Louis, whose countenance exhibited no change, and whose lips were close and motionless, was instantly complied with; but the deceiver, in order to mend his finances for the accomplishment of the marriage-contract, applies to one Cornu, an old and rich banker at Lyons, who had accumulated immense wealth by usury and extortion, and was haunted by remorse of conscience. After some conversation on demons and fpeckles, the pains of purgatory, &c. during an interval of silence, a voice is heard like that of the banker's deceased father, complaining of his dreadful situation in purgatory, and calling upon him to rescue him from thence, by putting into the hands of Louis Brabant, then with him, a large sum for the redemption of Christians in slavery with the Turks; threatening him at the same time with eternal damnation, if he did not expiate his own sins. Upon a second interview, in which his ears were falted with the complaints and groans of his father, and of all his deceased relations, imploring him for the love of God, and in the name of every saint in the Calendar, to have mercy on his own soul and others, Cornu obeyed the heavenly voice, and gave Louis ten thousand crowns, with which he returned to Paris, and married his mistress. The mifer, being afterwards undeceived, was so mortified, that he took to his bed and died.

The abbé de la Chapelle takes occasion to account for all the circumstances attending Saul's conference with the Witches of Endor, (which see,) and endeavours to shew that the speech, suppos'd to be addressed to Saul by the ghost of Samuel, actually proceeded from the mouth of the reputed forceress, whom he suppos'd to have been a capital ventriloquist. On these grounds he explains that transfiguration, and reconciles all its circumstances to the relation given of it in Scripture; where, it is to be observed, that Saul is not said to have seen Samuel, but only to have heard a voice, which a ventriloquist can produce and transmit from any quarter, and with any degree of strength whatever. He afterwards brings many inferences to prove, that the ancient oracles principally supported their credit, and derived their influence, from the exercice of this particular art. Many other learned men have given the same account of the witch of Endor. Though they all acknowledge a familiar spirit, yet the Hebrew word שן, and the plural שן, is generally rendered by the LXX ἄνεργον, ventriloquent. Thus it is rendered Isaiah, xix. 3. It appears from Plutarch (De Defect. Orac. tom. ii. p. 444.), Suidas (tom. i. ad voc. ἄνεργος-μύθος, p. 669.), and Josephus (Antiq. lib. xiv. p. 354.), that those who were anciently called ventriloquists had afterwards the name of Pythomæsters, which implies a pretence to divination. Accordingly Πυθός is the word used by the Vulgate version, 1 Sam. xxviii. 7, 8; though not, as Voltaire seems to intimate, in the Hebrew; and, therefore, there is no ground for the conclusion which he draws, viz. that the history was not written till the Jews traded with the Greeks, after the time of Alexander, i.e. for determining the date of a Hebrew book from the use of a word in a Latin translation, made many hundred years after it, and not to be found in the original.

From baron de Mengen's account of himself, and the observations made by M. de la Chapelle in his frequent examinations of M. St. Gilles, it seems that the fictitious voice produced by a ventriloquist does not (as the etymology of the word imports) proceed from the belly, but is formed in the inner parts of the mouth and throat. The art, according to this author, does not depend on a particular structure or organization of these parts, peculiar to a few individuals, and very rarely occurring, but may be acquired by almost any ardent person in attaining it, and determined to persevere in repeated trials. The judgments we form concerning the situation and distance of bodies, by means of the senses mutually assisting and correcting each other, seem to be entirely founded on experience (see Reid's Inquiry into the Human Mind, p. 70, edit. 2d,) and we pass from the sign to the thing signified by it immediately, or at least without any intermediate steps perceptible to ourselves. Hence it follows, that if a man, though in the same room with another, can by any peculiar modification of the organs of speech produce a sound, which in fineness, tone, body, and every other sensible quality, perfectly resembles a sound delivered from the roof of an opposite house, the ear will naturally, without examination, refer it to that situation and distance; the sound which the person hears being only a sign, which from infancy he has been accustomed, by experience, to associate with the idea of a person speaking from a housetop. A deception of this kind is practised withucces on the organ, and other musical instruments; and there are many similar optical deceptions.

Rolandus, in his Agologeton, mentions, that if the mediastrum, which is naturally a single membrane, be divided into two parts, the speech will seem to come out of the breast; so that the by-handlers will fancy the person possessed.

For some facts and observations tending to explain the curious phenomena of ventriloquism by Mr. John Gough, we refer to the Manchester Memoirs, vol. v. part 2. p. 628. London, 1802, in which the ingenious author investigates the method whereby men judge by the ear of the position of sonorous bodies relative to their own persons. This author observes in general, that a sudden change of direction in found, our knowledge of which, as he conceives, does not depend on the impulse in the ear, but on other facts, will be perceived, when the original communication is interrupted, provided there be a sensible echo. This circumstance will be acknowledged by any person who has had occasion to walk along a valley, intercepted with buildings, at the time that a peal of bells was ringing in it. For the sound of the bells, instead of arriving constantly at the ears of a person so situated, in its true direction, is frequently reflected in a short time from two or three different places. These deceptions are in many cases so much diversified by the succeffive interpositions of fresh objects, that the steeple appears, in the hearer's judgment, to perform the part of an expert ventriloquist on a theatre, the extent of which is adapted to its own powers, and not to those of the human
voice. The similarity of effect which connects this phenomenon with ventriloquism convinced the author, whenever he heard it, that what we know to be the cause in one instance is also the cause in the other, viz. that the echo reaches the ear, while the original sound is intercepted by accident in the case of the bells, but by art in the case of the ventriloquist. In order that the cause which gives rise to the amusing tricks of this uncommon talent may be pointed out with the greater clearness, it will be proper to describe certain circumstances that take place in the act of speaking, because the skill of the ventriloquist seems to consist in a peculiar management of them. Articulation is the art of modifying the sound of the larynx, by the assistance of the cavity of the mouth, the tongue, teeth, and lips. The different vibrations, which are excited by the joint operation of the several organs in action, pass along the bones and cartilages, from the parts in motion to the external teguments of the head, face, neck, and chest; from which, a succession of similar vibrations is imparted to the contiguous air, thereby converting the superior moiety of the speaker's body into an extensive field of sounds, the object of general opinion, which supposes the passage of the voice to be confined to the opening of the lips.

When an orator addresses an audience in a lofty and spacious room, his voice is reflected from every point of the apartment, of which all present are made sensible by the confused noise that fills up every pause in his discourse; nevertheless, every one knows the true place of the speaker, because his voice is the prevailing sound at the time. But were it possible to prevent his words from reaching any one of the audience directly, what would then follow? Undoubtedly a complete case of ventriloquism would be the consequence, and the person so circumstanced would transport the orator, in his own mind, to the place of the principal echo, which would perform the part of the prevailing sound at the instant. This he would be obliged to do, because the human judgment is bound, by the dictates of experience, to regard the person as incapable of the voice; and the deception in question would be unavoidable, being produced by the same cause and means of causes which makes a peel of bells, situated in a valley, seem to change place in the opinion of a traveller. It is the business of a ventriloquist to amuse his admirers with tricks resembling the foregoing delusion; and it will be readily granted, that he has a subtle fene, highly corrected by experience, to manage, on which account the judgment must be cheated as well as the ear. This can only be accomplished by making the pulses, constituting his words, strike the heads of his hearers, not in the right lines that join their persons and his. He must, therefore, know how to disguise the true direction of his voice, because the artifice will give him an opportunity to substitute almost any echo he chooses in the place of it. But the superior part of the human body has been already proved to form an extensive field of sound, from every point of which the pulses are repelled, as if they diverged from a common centre. This is the reason why people, who speak in the usual way, cannot conceal the direction of their voices, which in reality fly off towards all points at the same instant. The ventriloquist, therefore, by some means or other, acquires the difficult habit of contracting the field of sound within the compass of his lips, which enables him to confine the real path of his voice to narrow limits. For he, who is master of the art, has nothing to do but to place his mouth obliquely to the company; and to dart his words, if the expedition may be used, against an opposing object, whence they will be reflected immediately, so as to strike the ears of the audience from an unexpected quarter, in consequence of which the reflector will appear to be the speaker. Nature seems to fix no bounds to this kind of deception, only care must be taken not to let the path of the direct pulses pass too near the head of the person who is to be played upon; for, if a line, joining the exhibitor's mouth and the reflecting body, approach one of his ears too nearly, the divergency of the pulses will make him perceive the voice itself, instead of the reverberated sound.

The author has given the following narrative of a ventriloquist, whom he attended in the exercise of his art. His audience was arranged in two opposite lines, corresponding to the two sides of a long narrow room. The benches on which they were seated reached from one end of the place to the middle of it, the other part remaining unoccupied. The facts exhibited by him were the three following: First: he made his voice heard from behind his audience, but it never seemed to proceed from any part of the wall, near the heads of the people present; on the contrary, it was always heard resembling the voice of a child, who seemed to be under the benches. He stood during the time of speaking in a sloping posture, having his mouth turned towards the place from which the sound issued; so that the line, joining his lips and the reflecting object, did not approach the ears of the company. Second: advancing into the vacant part of the room, and turning his back to the audience, he made a variety of noises, that seemed to proceed from an open cupboard which flew directly before him, at the distance of two or three yards. Third: he placed an inverted glass cup on the hands of his hearers, and then imitated the cries of a child confined in it. His method of doing it was this; the upper part of the hearer's arm laid close along his side; then the part below the elbow was kept in a horizontal position, with the hand turned downwards, which was done by the operator himself. After taking these preparatory steps, the man bent his body forwards in a situation which presented the profile of his face nearly to the front of his hearer, whilist his mouth pointed to the cup; in which posture he copied the voice of a confined child so completely, that three positions of the glas were easily distinguished by as many different tones, viz. when he prefixed the mouth of the cup close against the palm, when one edge of it was elevated, and when the vessel was held near the hand, but did not touch it. The second and third instances of ventriloquism afford strong proofs, that this delusive talent is nothing more than the art of subduing an echo for the primary found; for, besides the change perceivable in the direction of the voice, it was found to be blended with a variety of secondary sounds; such as we know by experience are produced, as often as a noize of any kind issues from a cavity.

The method of preventing the vibration of the vocal organs from reaching the external extremities is still wanting, as our author acknowledges, to complete his theory of ventriloquism; and this, he presumes, can only be supplied by an adept in this art.
Thus we say, twelve of the affixes ought to be of the same flux where the demand is made.

In transitory actions, the courts will very often change the venue, or county, in which the cause is to be tried. The statute 6 Ric. II. cap. 2. having ordered all writs to be laid in their proper counties, this, as the judges conceived, empowered them to change the venue, if required, and not to insist rigidly on abating the writ, which practice began in the reign of James I. and this power is deliberately exercised, so as not to cause, but prevent a defect of justice. Therefore the court will not change the venue to any of the four northern counties, previous to the spring circuit; because there the affixes are held only once a year, at the time of the summer circuit. And it will sometimes remove the venue from the proper jurisdiction, (especially of the narrow and limited kind,) upon a juggulion, duly supported, that a fair and impartial trial cannot be had therein. Blackett. Comm. book ii.

VENUS, in Astronomy, one of the inferior planets; denoted by the character ☉.

Venus is easily distinguished by her brightness and whiteness, which exceeds that of all the other planets; and which is so considerable, that, in a dusty place, the projects a sensible shadow. Her place is between the earth and Mercury.

She constantly attends the sun, and never departs from him above 47° 48' or 44° 57'. If S be the sun (Plate XXI. Astronomy, fig. 8.), E the earth, V Venus or Mercury, and E a tangent to the orbit of the planet, then will the angle SEV be the greatest elongation of the planet from the sun; which angle, if the orbits were circles having the sun in their centre, would be found by finding: ES : SV :: rad. : tan. S.E.W. But the orbits are not circular, in consequence of which the angle EVS will not be a right angle, unless the greatest elongation happens when the planet is at one of its apsides. The angle SEV is also subject to an alteration from the variation of S.E. and SV.

The greatest angle SEV happens, when the planet is in its aphasis, and the earth in its perihelion, and the leaves angle SEV, when the planet is in its perihelion, and the earth in its apogee. M. de la Lande has calculated these greatest elongations, and finds them 47° 48' and 44° 57' for Venus, and 28° 20' and 17° 36' for Mercury. If we take the mean of the greatest elongations of Venus, which is 46° 22', it gives the angle VSE = 43° 37'; and as the difference of the daily mean motions of Venus and the earth about the sun is 37', we have 37': 43° 37': 1 day: 70-7 days, the time that would elapse between the greatest elongations and the inferior conjunction, if the motions had been uniform, which will not vary much from the true time.

See Elongation.

To find the position of a planet when stationary. Let S be the sun (fig. 9.), E the earth, P the contemporary position of the planet, X the sphere of the fixed stars, to which we refer the motions of the planets; let E, F, Q, be two indefinitely small arcs described in the same time, and let E, F, Q, produced, meet at L; then it is manifest, that whilst the earth moves from E to F, the planet appears stationary at L; and on account of the immense distance of the fixed stars, E.L., E.Q., may be considered as parallel. Draw S.E. S.F., S.P., and S.Q.; then, as E.P. and E.Q. are parallel, the angle QFS = EFS = P or S = P.S. = F.S. = E.F., and S.P. = S.Q. = F.Q. = S.E. = P.E. = P.S. = P.Q.; thus is, the contemporary variations of the angles E and P are as E.S.F. : P.S.Q., the contemporary variations of the angular velocities of the earth and planet versus (because the angular velocities are inversely as the periodic times, or inversely in the sesquiplicate ratio of the distances) as SP² : SE², or (if SP : SE :: a : 1) as a² : 1. But sin. S.E.P. = sin. S.P.E. being as S.P : S.E., or a : 1, the contemporary variations of these angles will be as their tangents. Hence, if x and y be the sines of the angles S.E.P. and S.P.E., we have x : y :: a : 1, and

\[
\frac{x}{\sqrt{1 - x^2}} : \frac{y}{\sqrt{1 - y^2}} :: a^2 : 1, \text{ whence } x^2 = a^4 - a^2
\]

\[
= a^2 + a + 1, \text{ and } x = \frac{a}{\sqrt{a^2 + a + 1}}, \text{ the sine of the planet's elongation from the sun, when stationary.}
\]

Ex. If P be the earth, and E Venus; and we take the distances of the earth and Venus to be 100000 and 72333, we find x = 0.48264 the sine of 28° 51' 5", the elongation of Venus when stationary, upon the supposition of circular orbits.

For eccentric orbits, the points will depend upon the position of the apsides and places of the bodies at the time.

We may, however, get a very near approximation thus. Find the time when the planet would be stationary, if the orbits were circular, and compute for several days, about that time, the geocentric place of the planet, so that you get two days, on one of which the planet was direct, and on the other retrograde, in which interval it must have been stationary, and the point of time when this happened may be determined by interpolation.

To find the time when a planet is stationary, we must know the time of its opposition, or inferior conjunction. Let m and n be the daily angular velocities of the earth and planet about the sun, and v the angle P.S.E., when the planet is stationary; then m - n, or n - m, is the daily variation of the angle at the sun between the earth and planet, according as it is a superior or inferior planet; hence, m - n, or n - m :: v :: 1 day :: \(\frac{v}{m - n}\), or \(\frac{v}{n - m}\), the time from opposition or conjunction to the stationary points both before and after. Hence, the planet must be stationary twice every synodic revolution.

Ex. Let P be the earth, E Venus; then the angle S.P.E. = 20° 51' 5"; therefore, P.S.E. = 13°; also, n = m = 3°; hence, 37° : 13° :: 1 day : 21 days, the time between the inferior conjunction and stationary positions.

If the elongation be observed when stationary, we may find the distance of the planet from the sun, compared with the earth's distance, supposed to be unity. For \(x^2 = \frac{a^2}{a^2 + a + 1}\); hence, \(a^2 + \frac{x^2}{x^2 - 1} \times a = - \frac{x^2}{x^2 - 1}\)

\(=\) if \(t = \) the tangent of the angle whose sine is \(x\), \(a = t^2 + \frac{1}{t^2} + \sqrt{\frac{1}{t^2} + 1 + \frac{1}{t^2}}\), upon the supposition of circular orbits.

A superior planet is retrograde in opposition, and an inferior planet is retrograde in its inferior conjunction; for let P be the earth (fig. 10.), if a superior planet be in opposition; then, as the velocities are as the inverse square roots of the earth of the orbits, the superior planet moves slower; hence, if E, F, Q, be two indefinitely small contemporaneous arcs, P.E. is less than E.F., and on account of the immense distance of the sphere Z of the fixed stars, E.P. must cut E.P. in some point x between P and z, consequently the planet appears retrograde from m to n. If P be the earth, and E an inferior planet in inferior conjunction, it will appear
Venus.

Pear retrograde from \( v \) to \( w \). These retrograde motions must necessarily continue till the planets become stationary. Hence, a superior planet appears retrograde from its stationary point before opposition to its stationary point after; and an inferior planet, from its stationary point before inferior conjunction to its stationary point after.

When Venus appears well to the fun, that is, from her inferior conjunction to her superior, the risings before him, and is called Phosphorus, or Lucifer, or the Morning star; and when she appears east of the sun, that is, from her superior conjunction to her inferior, the sets after him, or in the evening after her sets, and is called Hesperus, or Vesper, or the Evening star: being each in its turn for two hundred and ninety days.

To delineate the appearance of a planet at any time. Let \( S \) be the fun (fig. 11.), \( E \) the earth, \( V \) Venus, for example; \( aVb \) the plane of illumination perpendicular to \( SV \), \( cVd \) the plane of vision perpendicular to \( E \), and draw \( aVc \) perpendicular to \( c \); then \( eVd \) is the breadth of the visible illuminated part, which is projected by the eye into \( ec \), the vered fine of \( C \) with \( SV \), or \( SVZ \), for \( SV \) is the complement of each. Now the circle terminating the illuminated part of the planet, being seen obliquely, appears to be an ellipse; therefore, if \( cm \) represent the projected hemisphere of Venus next to the earth, \( mn \), \( cd \), two diameters perpendicular to each other, and we take \( ec = eV \) the vered fine of \( SV \), and describe the ellipse \( mn \), then \( ec \) is the axis minor, and \( mVn \) will represent the visible illuminated part, as it appears at the earth; and from the property of the ellipse, this area varies as \( ec \). Hence, the visible illuminated part: the whole disk: the vered fine of \( SV \): diameter.

Hence, Mercury and Venus will have the same phases from their inferior to their superior conjunction, as the moon has from the new to the full; and the same from the superior to the inferior conjunction, as the moon has from the full to the new. Mars will appear gibbous in quadratures, as the angle \( SVZ \) will then differ considerably from the two right angles, and consequently the vered fine will sensibly differ from the diameter. For Jupiter, Saturn, and the Georgian, the angle \( SV \) never differs enough from two right angles to make those planets appear gibbous, so that they always appear full-orbed.

Dr. Halley propounded the following problem: To find the position of Venus when brightest, supposing it's orbit, and that of the earth, to be circles, having the fun in their centre. Draw \( S \) perpendicular to \( E \), and put \( a = SE \), \( b = SV \), \( x = EV \), \( y = Vr \); then \( b - y \) is the vered fine of the angle \( SV \), which vered fine varies as the illuminated part; and as the intensity of light varies inversely as the square of its distance, the quantity of light received at the earth varies as \( \frac{b - y}{x^2} = \frac{b - y}{x^2} \times \frac{y}{x^2} \); but

\[
a^2 = b^2 + x^2 + 2 \times y; \quad \text{hence,} \quad y = \frac{a^2 - b^2 - x^2}{2 \times x^2};
\]

substitute this for \( y \), and we get the quantity of light to be as

\[
\frac{b - a}{x^2} = \frac{b^2 - a^2}{2 \times x^2} = \frac{2 \times b \times x - a^2 + b^2 + x^2}{2 \times x^2} = \text{a maximum};
\]

put the fluxion = 0, and we get \( x = \sqrt{3a^2 + b^2} - 2b \). Now, if \( a = 1 \), \( b = 2.7233 \), as in Dr. Halley’s tables, then \( x = 4.3035 \); hence, the angle \( ESV = 22^\circ 21' \), but the angle \( ESV \), at the time of the planet’s greatest elongation, is \( 43^\circ 40' \); hence, Venus is brightest between its inferior conjunction and its greatest elongation; also, the angle \( SEV = 39^\circ 44' \), the elongation of Venus from the sun at the same time, and \( \angle SV = VSE + VES = 62^2 5' \), the vered fine of which is \( 0.53 \), radius being unity; hence, the visible enlightened part: whole disk: \( 0.53 : 2 \); Venus, therefore, appears a little more than one-fourth illuminated, and answers to the appearance of the moon when five days old. Her diameter here is about 36', and therefore the enlightened part is about 10'.25. At this time, Venus is bright enough to cast a shadow at night. This situation happens about 36 days before and after its inferior conjunction; for, supposing Venus to be in conjunction with the sun and when seen from the fun to depart from the earth at the rate of 37' in 6 days, we have \( 37' = 22° 21' \): 1 day: 36 days near; the time from conjunction till Venus is brightest.

If we apply this to Mercury, \( b = 23.71 \), and \( x = 1.00058 \); hence, the angle \( ESV = 78° 55' \); but the same angle, at the time of the planet’s greatest elongation, is \( 69° 15' \). Hence, Mercury is brightest between its greatest elongation and superior conjunction. Also, the angle \( ESV = 22° 18' \), the elongation of Mercury at that time.

When Venus is brightest, and at the same time at its greatest north latitude, it can then be seen with the naked eye at any time of the day, when it is above the horizon; for when its north latitude is the greatest, it rides highest above the horizon, and therefore is more easily seen, the rays of light having to come through a less part of the atmosphere, the higher the body. This happens once in about eight years, Venus and the earth returning to the same parts of their orbits after that interval of time. Vince’s Elements of Astronomy.

The diameter of Venus is to that of the earth as 11:7 to 10 nearly, her apparent diameter equal to 50', and real diameter equal to 9330 miles; her apparent diameter, when reduced to the mean distance of the earth, is, according to Dr. Herchel, 18°79, and her real diameter a little larger than that of the earth (see Planets); her horizontal parallax about 30'; her distance from the sun is to that of the earth from the sun as 72333 to 100000; and her real distance is 68,914,866 miles; her excentricity is \( 2.5 \) of her mean distance from the sun (see Excentricity); the inclination of her orbit to the plane of the ecliptic \( 13^0 23' 35' \); her periodic course round the fun is performed in two hundred and twenty-four days seventeen hours nearly; and her motion round her own axis in twenty-three hours, or, according to the observations of Bianchi, in twenty-four days eight hours: according to Dr. Herchel, uncertain, but not so slow as twenty-four days. See Diameter, Distance, Excentricity, Node, Parallax, and Period. See also Planets, Planetarium, and Solar System.

Venus, when viewed through a telescope, is rarely seen to shine with a full face, but has phases just like those of the moon; being now gibbous, now horned, &c. and her illuminated part is conflantly turned towards the sun, i.e. it looks towards the east, when Phosphorus; and towards the west, when Hesperus.

These different phases of Venus were first observed by Galileo, who thus fulfilled the prediction of Copernicus: for when this excellent astronomer revived the ancient Pythagorean syllem, affirming, that the earth and planets moved round the sun, it was objected that in such a case the phases of Venus should reembrace those of the moon; to which Copernicus replied, that some time or other that resemblance would be found out. Galileo sent an account of the first discovery of these phases in a letter, written from Florence in 1611, to William de Medici, the duke of Tuscany’s ambaassador at Paris; defering him to communicate it
it to Kepler. The letter is extant in the preface to Kepler's Dioptrics, and a translation of it may be seen in Smith's Optics, p. 416.

Having recited the observations which he had made, he adds, "we have hence the most certain, undeniable evidence and demonstration of two grand questions, which to this day have been doubtful and disputed among the greatest masters of reason in the world. One is, that the planets in their own nature are opaque bodies, contributing to Mercury what we have seen in Venus; and the other is, that Venus necessarily moves round the sun, as also Mercury, and the other planets; a thing well believed indeed by Pythagoras, Copernicus, Kepler, and myself, but not yet proved, as now, by ocular inspection upon Venus." He concludes with explaining the cypher that had been sent, in the following words: "Hec immatura a me frustra leguntur, i.e. Cynthiae figuras emulatur mater amorum, or, Venus imitates the phases of the moon."

M. Maraldi made several observations on Venus in 1729, but could perceive no spot; and therefore, these observed by Bianchinii must either have disappeared, or the air at Paris was not so clear as at Rome.

Martin Folkes, eq. former president of the Royal Society, spoke of Bianchinii with respect, as too accurate to make any mistakes in astronomical observations, and too honest to publish any thing that was not exactly agreeable to truth. See Nature of the Planets.

Sometimes Venus is seen in the disc of the sun, in form of a dark round spot. This happens when the earth is about her nodes at the time of her inferior conjunction. These appearances, called transits, happen but seldom. We have had two in the last century, viz. one in June 1761, and another in June 1769. The next will not occur before the year 1784. See Parallax.

The effect of the parallax being determined, for computing which Dr. Maskelyne proposed a new method in relation to the transit of Venus in 1769, the transit affords a very ready method of finding the difference of the longitudes of two places where the same observations are made. For compute the effect of parallax in time, and reduce the observations at each place to the time, if seen from the centre of the earth, and the difference of the times is the difference of the longitudes. From the mean of sixty-three results from the transits of Mercury, Mr. Short found the difference of the meridians of Greenwich and Paris to be 9° 15'; and from the transit of Venus in 1761, to be 9° 10' in time.

Except such transits as these, Venus exhibits the same appearances to us regularly every eight years; her conjunctions, elongations, and times of rising and setting, being very nearly the same, on the same days, as before.

In 1672 and 1686, Caffini, with a telescope of 34 feet, thought he saw a satellite moving round this planet, and distant from it about three-fifths of Venus's diameter. It had the same phases as Venus, but without any well-defined form; and its diameter scarcely exceeded one-fourth of that of Venus. Dr. Gregory (Ar. lib. vi. prop. 3.) thinks it more than probable that this was a satellite; and supposes the reason why it is not usually seen, to be the insufficiency of its surface to reflect the rays of the sun's light; as is the case of the spots in the moon; of which, if the whole disc of the moon were composed, he thinks, that planet could not be seen as far as to Venus.

Mr. Short, in 1740, with a reflecting telescope of 15 inches focus, perceived a small star near Venus; with another telescope of the same focus, magnifying fifty or sixty times, and fitted with a micrometer, he found its distance from Venus about 10°; with a magnifying power of 240, he observed the star always the same phases with Venus; its diameter seemed to be about one-third, or somewhat less, of the diameter of Venus; its light not so bright and vivid, but exceeding sharp and well defined. He viewed it for the space of an hour, but never had the good fortune to see it after the first morning. Phil. Trans. N. 359. p. 645, or Martyn's Abr. vol. viii. p. 208.

M. Montaigne, of Limoges in France, we are told in the Encyclopédie, art. Venus, preparing for observing the transit of 1761, discovered in the preceding May a small star near the distance of 26 from Venus, and its diameter was about one-fourth of the planet. He made other observations for several days, which were communicated to M. Boudin, who read two memoirs on the subject to the Royal Academy of Sciences, in which he endeavoured to state the elements of the orbit of this satellite; but it is to be considered, that Montaigne's telescope had no micrometer, and that his distances must be very vague and uncertain. If Venus has a satellite, it must, according to Dr. Herschel, be less in appearance than a star of the eighth or ninth magnitude. Phil. Trans. for 1755.

After all, it must be acknowledged, that Venus may have a satellite, though it is difficult for us to see it. Its enlightened side can never be fully turned towards us, but when Venus is beyond the sun; in which case, Venus appears little bigger than an ordinary star, and, therefore, her satellite may be too small to be perceived at such a distance. Whether it is between us and the sun, her full moon has her dark side turned towards us; and when Venus is at her greatest elongation, we have but one half of the enlightened side of her full moon towards us, and even then it may be too far distant to be seen by us. But it was presumed, that the two transits of 1761 and 1769, would afford opportunity for determining this point; and yet we find that, although many observers directed their attention to this object, no satellite was seen in the sun's disc; and, therefore, it is reasonable to conclude, that Venus has no satellite.

The phenomena of Venus evidently show the falsity of the Ptolemaic system: for that system supposes, that Venus's orb, or heaven, includes the earth, passing between the sun and Mercury. And yet all our observations agree, that Venus is sometimes on this side of the earth, and sometimes on the other; nor did ever any body for the earth between Venus and the sun; which yet must frequently happen, if Venus revolved round the earth in an heaven below the sun.

Dr. Desaguliers contrived a planetarium to represent the phenomena of Venus, according to the discoveries of Bianchinii; as did also Mr. Ferguson an orrery for the same purpose. The principal properties of these machines are the following: that the angle of the axis of the globe representing Venus makes, with the ecliptic, an angle of 15°; that the tropics are 75° from the equator; that the tropics are 15° from the equator; that the plane of a polar horizon for the longest day cuts the plane of the equator at an angle of 15°; that the sun's greatest declination is 55°; that there are but 93 days in every revolution round the sun; and that to bring the days to an even reckoning, every fourth year must be a leap year, which, taking in the four quarters of a revolution, will make the leap year in Venus count of ten of her days, equal to 24 months of our time; and that the long day for the north pole will contain 43 apparent diurnal revolutions of the sun. For a detail and illustration of the phenomena resulting from these properties, see Desaguliers's Exp. Phil. vol. i. p. 552, &c. Phil. Trans. vol. xvi. p. 127, &c. Ferguson's Alman. p. 8, &c. For the history and account of various instruments of this kind, see Observ. and Planetarium.

Venus.

Explanation of the Tables.—Table I. contains the epochs of the mean longitude of the aphelion and node. Table II. contains the mean motions of the same, for years. Table III. contains their mean motions for days. Table IV. contains their mean motions for hours, minutes, and seconds. Table V. contains the equation of the orbit for the year 1780; but this equation diminishes 25" in 100 years. Table VI. contains the logarithm of the distance of Venus from the Sun, for the year 1780, with the corrections for 100 years, owing to a change of the eccentricity. Table VII. contains the heliocentric latitude of Venus, the reduction in longitude to the ecliptic, and the reduction of the logarithm of the distance, in order to get the curvate distance from the Sun.

The greatest equation (Table V.) of the orbit is 47' 20", and this diminishes at the rate of 25" in 100 years; that is, the diminution for every minute of the equation is very nearly 0".5; we shall, therefore, take the secular diminution at the rate of 0".5 for every minute of the equation: thus, if the equation be 16', the diminution is 4" for 100 years; and for any other number of years, the diminution is in proportion. For any time before 1780, this correction must be added to the equation.

In Table VI. there is a small table for the correction of the logarithms of the distance of Venus from the Sun, for 100 years; entering it with the mean anomaly of Venus, and applying the correction according to the sign, for any time after 1780; but with a contrary sign, before 1780.

To find the heliocentric Latitude and Longitude of Venus, and the Logarithm of her Distance from the Sun.—From Table I. take out the epochs of the mean longitude, the aphelion and node, for the given year; and place them in a horizontal line. But if the given year be not found in that Table, take the nearest year preceding the given year, as an epoch, and take out as before; under which (Table II.) place the mean motion in longitude, of the aphelion and node, answering to the number of years elapsed since the epoch, to the given year.

Under these, write down (Table III.) the mean motions of the fame, for the given day of the month.

Under these, write down (Table IV.) the mean motions of the fame, for the given hours, minutes, and seconds.

Add together the numbers in the several columns, regarding 12 S. or any multiple thereof, if they occur, and you get the mean longitude, places of the aphelion and node, for the given time.

Subtract the longitude of the aphelion from the mean longitude, and the remainder is the mean anomaly.

With the mean anomaly enter Table V., and take out the equation of the orbit with its proper sign, making proportion for the minutes and seconds, if there be any. But this requires a correction, at the rate of 0".5 for every minute of the equation for 100 years; and for any other time, the correction will be in proportion; to be subtracted after 1780, and added before that time.

Apply the equation with its proper sign to the mean longitude, and you get the longitude on the orbit, from the mean equinox.

From the longitude of Venus in her orbit, subtract the longitude of the node; and you have the argument, called the Argument of Latitude.

To the longitude on the orbit, apply the reduction (Table VII.) with its proper sign, and you have the longitude upon the ecliptic, from the mean equinox.

To the longitude thus found, apply the nutation with its proper sign, and you get the true longitude of Venus on the ecliptic, from the true equinox.

With the argument of latitude enter Table VII., and take out the latitude, making proportion for the minutes and seconds, if necessary; and this is the true heliocentric latitude of Venus.

With the mean anomaly of Venus enter Table VI., and take out the logarithm of her distance from the Sun, making proportion for the minutes and seconds, if necessary. But this must be corrected by the small Table, to be entered with the mean anomaly, and you get the correction for 100 years; and for any other time, the correction will be in proportion, to be applied with a contrary sign, before 1780.

With the argument of latitude enter Table VII., and take out the reduction in the column under Sub. Log., making proportion for the minutes and seconds, if necessary; and subtract it from the logarithm of the distance last found, and you have the logarithm of the curvate distance.

Ex.—On June 23, 1690, new style, at 1° 14' 11" mean time at Greenwich; to find the heliocentric latitude and longitude of Venus, and the logarithm of her distance from the Sun.

VENUS.

Venous, in Chemistry, is used for the metal Copper; which fee. Its character is $\frac{2}{3}$; which, say the adepts, express it to be gold, only joined with some corrosive and arilenchial menstruum; which, removed, copper would be gold.

Venus is universally allowed, by the chemists, &c. to be one of the most powerful medicines in nature; and sometimes, upon having been compos’d the famous Butler’s stone, which cured maff of diseases by only licking it. Of this is compos’d that noble remedy of Van Helmont, viz. the sulphur of vitriol, or ens vitrioli, fixed by calcination and colobation. Of the ens vitrioli of Venus is likewise compos’d Mr. Boyle’s arcanum, the colochar vitrioli.

It is certain copper is a powerful emetic, and an antidote against poisons; for it is no sooner taken, than it exerts its force: whereas other vomitories lie a good while in the stomatch; but one single grain of dust of Venus immediately vomits. Hence syrups, that have flow’d over night in copper vessels, create a vomiting.

However, pure, copper, in its metallic state, or calcined by fire, appears to be indiffusible, and of no considerable effect, in the bodies of animals; but diffus’d in the nitrous or marine acids, and crystallized or excrusted by heat, it proves a strong caustic. Preparations of this kind, though formerly used, are now laid aside. Copper, combined with the vitriolic acid, or with vegetable acids, or corroded by the air, acts outwardly, as an efficacious detergent and a gentle echarotic, and internally as a virulent emetic and cathartic. Some have ventured on small doses, as quick emetics for expelling poisons; but the end may be obtained by lefs dangerous means.

It has been also reckoned an excellent medicine in chronic cafes: hence a famous physician is recorded to have cured Charles V. of a dropsy by the use of copper.

A faturated solution of the metal in volatile spirits is recommended by Boerhaave in disorders proceeding from an acid, weak, cold, phlegmatic cafe. He says, that if three drops be taken in the morning in a glafs of mead, and the dose doubled every day, to twenty-four drops, it proves attenuating, warming, and diuretic; that by this medicine he once cured a confirmed afces; though in other similiar cafes it failed; that it is the only preparation of copper which does not prove emetic; and that it may be tried with safety. Dr. Lewis, however, is of opinion, that in considerable doses it would exert the same virulent operation with the other soluble preparations or folutions of copper. A solid preparation of this kind, made by rubbing together in a glafs mortar two parts of blue vitriol, and three of the volatile salt, procured from sal ammoniac, till all effervescence has ceased, and then gently drying the concrete, is ordered in the last Edinburgh Pharmacopoeia, under the name of cuprum ammoniacum. It has frequently been given with success in epileptic and convulsive disorders. Lewis. See Sulphate of Copper. See also Sapphina Aqua, and Aqua Cupri Ammoniata.

Venus is diffoluble by all the salts known. Both acid, alkaline, and nitrous; may, even by water and air, considered as they contain salt.

It is from this common reception of all menstruums, that copper is called Venus, q. d. meretric pubes, a common prostitute: though others take the denomination to have been occasion’d by its turning of a sea-green colour, when diffolved by acid. It must be given internally, with great caution.

VENUS, CRYSTALS of. See CRYSTAL, VERDECRAINE, and COPPER.

VENUS, Spirit of. See ACETIC ACID.

Vol. XXXVI.
Celestis, that is to say, the planet of that name; and Astarte, the wife of Adonis, whose worship was intermingled with that of the planet, or, which comes to the same, that Syrian Venus, the fourth in Cicero, so celebrated in antiquity. The Phenicians, in conducting their colonies into the islands of the Mediterranean sea, and into Greece, introduced thither the worship of this goddess. They stopped first in the island of Cyprus, which lies next the coasts of Syria; and there the worship of this goddess was generally received. From thence they went to Cythera, an isle near the continent of Greece; there the Greeks began to traffic with them, and to get some knowledge of their religion; and this is the reason of their giving out, that it was near this island the goddess was seen for the first time, because it was there they came to hear of her first. A very convincing proof that the worship of Venus was established in that island, before it passed into the continent, is, that the temple of Cythera was accounted the most ancient of any that Venus had in Greece, as Pausanias remarks.

From Cythera the worship of this goddess passed into Greece; and as those who had brought it thither came by sea, the Greeks, who endeavoured to give every thing a marvellous dress, say she had sprung from the sea, and gave her the name of Aphrodite, a word which imports foam. This, no doubt, is the true explication of this fiction, and it is needless to search into it for any other mystery. The Greek poets embellished this fable according to their own fancy. Having heard of Astarte’s passionate love of Adonis, they took care to apply this circumstance to their Venus: and, moreover, they considered Love as the son of this goddess, and gave her the three Graces for her daughters. In fine, they formed that love-fable, of which the ideas have served, in after-ages, to embellish the works of their brother-poets. A young virgin rides out of the foam of the sea, and appears upon a shell-fish; she sits down on mount Cythera, where the flowers spring up under her fest; the Hours, charged with the care of her education, conducted her to heaven, where all the gods, charmed with her beauty, make love to her; she matches with Vulcan, the most deformed of all; the disgraces herself her gallantries with Mars and Mercury; by the one she has Cupid, and by the other Anti-Cupid; Bacchus is her ‘quire; in fine, she presides over marriages and gallantry; and, therefore, has a mysterious girdle given her, called the ceius of Venus, which not only makes herself amiable, but has virtue to kindle the flame of an extinguished passion, &c.

This was not all, they foisted into the history of the goddess Venus, most of the celebrated pieces of gallery. Some beauty being surprised in an intrigue, gave rise to the adultery of Mars with Venus, and to the stratagem of Vulcan. Venus, whatever might be the dishonourable ideas entertained concerning her, was nevertheless regarded as one of the principal deities; and as the patronized scandalous passions, she was worshipped in a manner worthy of her. Her temples, open to prostitution, taught the corrupt world, that in order to pay due honour to the goddess of love, they were to have no regard to the rules of modesty. The virgins prostituted themselves publicly in her temples, and there the married women shewed as little reserve. Amathus, Cythera, Gnidos, Paphos, Icalia, and the other places especially consecrated to this goddess, were disfigured by the most infamous abuses.

Farther, as there were several Veneus, her worship was not everywhere the same. In some places they only burned incense upon her altar; elsewhere they made her an offering of sweet odours, one ingredient of which was the fleth of a sparrow; in other places they sacrificed to her a white goat. The women had also a custom of confecting their hair to this goddess; and the trefoles of Berenice, which she had vowed to Venus, were placed among the fans.

Among the flowers, the rose was particularly consecrated to this goddess, because this flower had been tinged with the blood of Adonis, whom one of its thorns had wounded, which changed it into red from white, which it was before this adventure. The myrtle, too, was dedicated to her, because it commonly grows upon the borders of the water where this goddess was born. The swans and sparrows were particularly consecrated to her, but above all the pigeons, from the fable which lets forth, that while this goddess was one day playing with Cupid, the little god would needs wager to gather more flowers than thee, and a nymph named Perilerta, having alighted the gods, she won the wager, with which Cupid was so provoked, that he transformed the nymph into a pigeon. As there were several persons who bore the name of Venus, her worship was not every where the same.

Venus was known under several appellations and characters; derived either from the places where she was worshipped, or from some particular circumstances that had given rise to her worship. Accordingly we read of the Venus Amathusa, Amica, Acantha, Apatira or Deidrafo, Aphroditia, Archytis, Argynnis, Armata, Aurea, Barbata, Bebissi, Calypgia, Calus, Chacina, Colus, Cyprus, Cytheria, Elephanta, Elypo, Ergoria, Etaira, Gentixis, Hortenijis, Impoja, Lilibia, Marina, Nephe, Paphis, Praxis, Riden, Verticordia, Vitrix, Zeryntia, &c &c.

Praxiteles executed two statues of Venus, one clothed, bought by the inhabitants of Cos, and another naked, which he sold to the Cnidians. See ANADUOMEN, and VENUS de Medicis.

The Venus of M. Maffei seems to have been formed in conformity to the well-known passage of Terence,

"Sine Cerere & Baccho friget Venus."

The goddess in this statue is accompanied with two Cupids, and crowned with ears of corn, holding a thyrus, wrapped about with leaves and clusters of grapes; and as she carries in her hand three arrows, she seems to teach us that her arrows fly more unerring when Ceres and Bacchus concur. Pausanias informs us that he had seen in Elis a fine statue of Venus Urania or Celestial, whose feet rested upon the back of a tortoise; and another of terrestrial Venus, placing her feet upon a he-goat.

We have on medals the Venus Urania, or Celestis, with a star or sun, or celestial globe in her hand; and the Venus Paphia, almost naked, leaning on a column, with a helmet and the arms of Mars in her hands, bearing an inscription Veneri Vitricis, or Veneri Genetricis. She is sometimes seen armed, sometimes resting upon a dolphin, holding a pigeon in her lap, or with Adonis, accompanied by his dogs, or with Cupid and the three Graces; but more frequently rising from the sea, seated upon a shell borne by two Tritons, or upon a chariot drawn by two sea-horses, or by a female sea-goat, or rather he-goat; for, according to Pausanias, her statue, made by the famous statuary Scopas, was upon that animal, and in that case she is accompanied by Nereids and Cupids, mounted upon dolphins, one of the Nereids holding a lyre in her hand, and mounted upon a sea-centaur; but more frequently her chariot is drawn by swans or pigeons, birds consecrated to her. Sometimes she
she appears herself supported by a Triton, having a buckler in her hand, on which is represented a head; sometimes mounted upon sea-horses, she seems to skim over the waves of the sea, her head being covered with a veil which swells in the wind, with Cupid swimming at her side. An oak at the foot of the goddesfs seems to represent the Venus Pelagia or Marine; and the figure which she holds in her hand, a cornucopia, expresses the blemblings produced by maritime commerce. There is also a picture of the Venus Deidiofa in the Barberini palace at Rome, which is one of the finest-coloured pictures that is left us by the ancients; the hair of whose head may be compared with Guido's, and the colouring of the flesh reminds us of Titian. Part of this picture is lost, and part restored by Carlo Marat. Venus is described by Statius (Lib. i. 1. v. 56) much in the same manner as she is represented in the Barberini picture.

We shall only add, that Venus is sometimes described by the poets of the third age under the character of the goddesfs of jealously, rather than as the goddesfs of love; in which Valerius Flaccus (Argon. ii. v. 106.) and Statius (Theb. v. v. 69.) have drawn two very terrible pictures of her.

Spence's Polymetis, p. 74.

Venus de Medicis, in the history of Ancient Sculpture, a famous statue of white marble, about five feet high, brought from the Medicis palace at Rome to Florence, by order of duke Cosimo III., and now standing in the great duke's palace. The hips, legs, and arms, were broken off by the removal of this statue; but they have been rejoined with an art, that renders their former separation imperceptible. The inscription on the base intimates that this was the work of Cleomenes, an Athenian, the son of Apollodorus; the pedastal is modern; the statue seems to bear a little forwards; the right knee advances a little; the left-hand is placed before that part which distinguishes the sexes, and the right across her breasts; yet without touching the body. The head inclines a little to the left shoulder; so that her face seems to be turned away a little from the observer: and from this circumstance some have taken occasion to remark, that the hair of the head of this Venus expresses three different passions; as you first approach her, you perceive avenion or denial in her look; as you advance a step or two nearer, the fhow complaisance; and one step more to the right, it is said, turns into a little infectious and infulint fyllae: but Mr. Spence does not allow that this account is justified by the statue itself.

The attitude of the Venus de Medicis is particularly graceful; that attitude may be deferred in two verses of Ovid, Art. Am. v. 614.

"Ipfa Venus pubem, quiesque velamina ponit,
Protegitur levä femi-reducâ manu.
"

The bloom of youth, the pleasing softness of her look, and her beauty and modesty, seem to rival each other in the charms of her countenance. Her person is somewhat plump, and the flesh is fo admirably executed, that it seems fo soft as if it would yield to the touch. Time has given to the white marble a yellowish hue, though it is almost transparent; her hair is brown, which may be no more than the faded gilding not unusual among the ancients. The head, which is said to be too small in proportion to the other parts, is inscribed by fome not to have been executed by the fame artift who made the body: this will ever be the standard of female beauty and softness; the breasts are also the fmall that can be conceived, fmall, diftinct, and delicate, muffgleging an idea of softness, which no copies can imitate, and alo of firmnefs: from the breasts, her shape begins to diminish gradually down to her wait; but with an exquisifte fineness of shape, the Venus of Medicis has what the Romans call corpus solidum, and the French the enboupoint: and her wait in particular is not represented as flimed by art, but as exactly proportioned by nature to all the other parts of her body. There is also a tendernefs and elegance in every other part of her form: her legs are neat and fender: the small of them is finely rounded, and her feet are little, white and pretty: fo that the poiffeles all thofe leffer beauties which the poets have marked out in the female make; the testes fure (Hor. lib. ii. od. iv. ver. 21.), and the pes candidus (Id. lib. iv. od. i. v. 27.), and exiguis (Ovid. Am. lib. ii. el. iii. ver. 7.) and one may well fay of this statue, what one of the perfonf in Plautus's Epidicus (act v. fc. 11.) fays of a complete beauty:

"Ab unguiculo ad capillum summum, eft feluviifima."

Though the Venus of Medicis has not escaped fexure, with regard to the smallnefs of her head and hips, the large-ness of the nofe, the depth of the partition along the ver- tebrae of the back, the length of the fingers, which, excepting the little finger on the left-hand, are without joints; and though, in comparing the parts separate, as the head, nofe, &c. of this statue, with thofe of others, the familiar parts might be found even of superior workmanship; yet for such a combination of beauties, the delicacy of shape and attitude, and symmetry of the whole, it is universally allowed that the world doth not afford its equal. This incomparable statue flonds between two others, which in any other place would be esteemed admirable pieces: that on the right of the Venus de Medicis is twice as big, with the golden apple in her hand, and is called Venus Virile; the other, by Hercules Ferrata, is distinguished by the name of Venus Urania. Spence's Polymetis, p. 6, &c. Keyler's Travels, vol. i. p. 434.

Venus, in Heraldry, is used for the colour vert.

Venus, in the Linnean System of Natural History, a genus of the Telleaceae order of worms. See CONCHOLGY.

Venus, Mount of, Mona Veneris, among Anatamofis, is a little hairy protuberance in the middle of the pubes of women; occasioned by the collection of fat under the skin in that place.

Among choromancers, the mount of Venus is a little eminence in the palm of the hand, at the root of one of the fingers.

Venus's Comb, in Botany. See SCANDIX.

Venus's Fly-Trap. See Dionex.

Venus's Looking-Glass. See Campanula and Speculum Venerei.

Venus's Name-Wort. See Cotyledon, n. 19, and Cy- noglossum, n. 18.

Venus, Cape, in Geography, a cape on the coast of Ota- rieh. N. lat. 17° 29'. W. long. 149° 36'.

VENUSIA, VENOSA, in Ancient Geography, a town of Italy, in Apulia, near mount Vultur, watered by a small river called Aufidus. It is said to have been denominated Aphrodita. It became a Roman colony in 400 B.C. It was formerly a magnificent city, but its baths, theatres, and temples have been destroyed. It was the birth-place of Horace.

VENUSTI, MARCELLO, in Biography. This painter was born at Mantua in 1515, and was a pupil of Pierino del Vaga. He is however far better known as the painter of several designs of Michael Angelo, (to which he gave a colour unknown to that great compositor,) than by any ori-
ginal works of his own. The cardinal Farnese engaged him to copy the great work of the Laft Judgment in the Capella Scitina, upon a small scale, which he accomplished very much to the satisfaction of M. Angelo, who in consequence engaged him to paint an altar-piece for the Capella de Ceti in the church of La Pace, from a design of his own, of the Annunciation. There are several pictures in England, which are called Michael Angelo's, that have every appearance of being painted by Venuti. Some works of his own are spoken of with respect, particularly the Martyrdom of St. Catherine, in the church of S. Agostino; and St. John in the Wilderness, in St. Catherine alli Fumari. He died in 1576, aged eighty-one.

VENZONE, in Geography, a town of Italy, in the country of Friuli; on the Tajamari; 18 miles W.N.W. of Friuli.

VEPILIUM, or VEPILLUM, in Ancient Geography, a town of Africa, S. of Carthage, situated two leagues S.E. of Alama, which has still some villages of the Romans.

VEPRAECELUM, in Botany, the thirty-thirst natural order among the Fragments of Linnaeus, named from vepera, a briar or bramble, because the plants which compose this order are pliant shrubs, of humble growth. The genera mentioned at the end of the Genera Plantarum are Dais, Quisqualis, Diosa, Daphne, Cudnora, Lachnea, Pafferia, Stellera, and Thefium; to which Linnaeus has added in manuscript, Struthiola, Santalum (with a doubt whether it should not rather be referred to the Biconora), and Schranthus. No remark occurs, in Gikeke's publication of the Prelections of Linnaeus, on this order. As far as concerns the eight first named of the above genera, with Struthiola, it is precisely analogous to Juffieus's Thymellæa; see that article. Thesium and Santalum belong to Mr. Brown's Santalaceæ, an order extracted from the Onagraceæ and Elagni of Juffieu, which the reader will find in its proper place. Schranthus seems naturally one of the Caryophyllicæ, notwithstanding the infonation of its flamins into the tulip, which obliged Juffieu to range it with his Portulaceæ. Perhaps this decision may partly be supported by the habit, and the aspect of the flower.

VEPRIS, Juss. 371, a name given by Commerson to what is now called Scopolia; see that article.

VER-PUCERON, in Natural History, a name given to a kind of insects which are food of eating the puceron, and destroy them in vast numbers.

They are thus called, as the ant-eater is, formica-leo, from their destroying great numbers of them.

These ver-pucerons are a sort of worms produced from the eggs of flies, and are of two principal kinds; the one having legs, the other none.

When we observe the vast number of young produced by every puceron, and the quick progress they make in their multiplication, we are apt to wonder, that every plant and tree in the world are not covered with them; but on the contrary, when we observe the devastation these devours make among them, we are apt to wonder how any of them escape at all, to perpetuate the species. These worms indeed seem created for no other purpose but to destroy them; and this they do in so violent a manner as is scarcely to be conceived. As the flies of many kinds lay their eggs on meat and other substances, which they know will afford food for the young ones, when hatched from them; so the parents of these worms lay their eggs on the branches and leaves of trees loaded with pucerons, on which they know they will feed. The worms produced from them are devourers from the very instant they are hatched, and find themselves placed in the midst of prey, being every way surrounded by a nation of creatures which are their proper food, and which are furnished with no weapons, either offensive or defensive, and which never so much as attempt to fly from them, but seem wholly ignorant of their danger, till seized upon by the devourers. Reaumur's Hist. of Insects, vol. vi. p. 111.

The flies, which are produced from these worms, are all of the two-winged kind; but there are several different species of them; the generality of them resemble wasps, and have a very flat body. Goedart, who has described some of these flies, was surprized to see them very small when first produced from the chrysalis, yet growing very large in a quarter of an hour's time, and that without taking any nourishment; but this was only owing to their several parts having been squeezed while in the chrysalis, and expanding themselves when they were at liberty from the confinement. These are the changes of this kind of lea-puceron; but the other devourers of these creatures, which has fix legs, is of a different kind, and indeed is in itself reducible to several species, some of these fix-legged worms becoming four-winged flies, and others a kind of beetles. These, from their near resemblance to the fornicato, are by Reaumur disagreeably called puceron-lions.

Ver-Polye, a name given by Reaumur, and some other authors, to a species of water-worm, by no means to be confounded with the creature called simply the polype, and which is so famous for its reproduction of parts cut off, and for many other singular properties.

This ver-polpe is a species of water-worm, produced from the egg of a tipula, and had this name given it from some remarkable productions, placed at the anterior and posterior parts of the body, which are supposed to have some analogy with the parts of the sea-fish called the polypus. These worms are found in muddy ditches, usually either crawling upon, or buried in the mud. Reaumur's Hist. of Insects, vol. ix. p. 49.

VERA, in Ancient Geography, a town of Asia, in Media, on an eminence, and strong by its situation.—Alfo, the name of a river of Gaul.

VERA, in Geography, a town of Spain, in Navarre; 25 miles N. of Pamplona.—Alfo, a town of Spain, in the province of Grenada; 34 miles N.E. of Almeria. N. lat. 37° 8'. W. long. 2° 4'.—Alfo, a river of European Turkey, which runs into the gulf of Salonick, near the mouth of the Vardar.

Vera Billia. See Billa.

VERABADURGAM, in Geography, a town of Hindooftan, in Mylore; 8 miles W.S.W. of Caverpatam.

VERACINI, ANTONIO, in Biography, uncle and master to Francesco Maria Veracini, the celebrated performer on the violin, published at Florence, in 1629, ten fanatas, the usual number, till Corelli's time; and afterwards, "Sonate da Chiesa," two sets; but this author not being possessed of the knowledge, hand, or caprice of his nephew, his works are now not sufficiently interesting to merit further notice, particularly as there was nothing marked or original in his style; the harmony indeed was correct; but "much may be right, yet much be wanting."

VERACINI, FRANCESCO MARIA, a native of Florence, and contemporary with Tartini, who were regarded as the greatest masters of the violin that had ever appeared; nor were their abilities confined merely to the excellence of their performance, they extended to composition, in which they both manifested great genius and science. But whatever resemblance there may have been in the professional skill of these two masters, it was impossible for any two men to be more dissimilar,
Beating at Lucca at the time of La Felle della Croce, which is celebrated every year on the 14th of September, when it is customary for the principal professors of Italy, vocal and instrumental, to meet, Veracini entered his name for a solo concerto; but when he went into the choir, in order to take possession of the principal place, he found it already occupied by Padre Girolamo Laurenti, of Bologna; who, not knowing him, as he had been some years in Poland, alleged him where he was going? Veracini answered to the place of first violin. Laurenti then told him, that he had been always engaged to fill that post himself; but that if he wished to play a concerto, either at vespers, or during high masses, he should have a place assigned him. Veracini, with great contempt and indignation, turned his back on him, and went to the lowest place in the orchestra. In the act or part of the service in which Laurenti performed his concerto, Veracini did not play a note, but listened with great attention. And being called upon, would not play a concerto, but defined the hoary old father would let him play a solo at the bottom of the choir, defining Lanzetti, the violincellist of Turin, to accompany him; when he played in such a manner as to extort an equirel in the public church. And when he was about to make a recitativo, he turned to Laurenti, and called out: "Cofi fiuona per fare il primo violino: " ‘this is the way to play the first fiddle.’ Many silly stories of this kind are handed about Italy concerning the caprice and arrogance of this performer, who was usually qualified with the title of Capo fazzo. Veracini would give lefions to no one except a nephew, who died young. The only master he had himself in his youth, was his uncle, Antonio Veracini, of Florence; but travelling all over Europe he formed a style of playing peculiar to himself. Besides being in the service of the king of Poland, he was a considerable time at different courts of Germany, and twice in England, where, during the time of Farinelli, he composed several operas: among which was "Adriano," in London, in the winter of 1735 and 1736, which had a run of twelve nights; and in 1744, "L’Errore di Salomone," in which, Monticelli performed.

Veracini’s first arrival in England was in the year 1713, when in the advertisements of the time for the opera of Dorinda, it is said that “Signor Veracini, lately arrived, will perform symphonies;” and the same year, with the operas of Crefo, Arminio, and Erninelinda, folos on the violin were frequently performed by Veracini.

W. saw and heard him perform in the year 1745, at Hickford’s room, where, though in years, he led the band at a benefit concert for Jozzi, the second fiddle, at the opera, in such a bold and masterly manner as we had never heard before. Soon after this, in returning to the continent, Veracini was shipwrecked, and lost his two famous Steiner violins, thought to have been the best in the world, and all his effects. He used to call one of his violins St. Peter, and the other St. Paul.

As a composer he had certainly a great share of whim and caprice, but he built his fancies on a good foundation, being an excellent contrapuntist. The peculiarities in his performance were his bow-hand, his shake, his learned arpeggios, and a tone so loud and clear, that it could be distinctly heard through the most numerous band of a church or theatre.

Veracini and Vivaldi had the honour of being thought mad for attempting in their works and performance what many a fopper gentleman has since done encensured; but both these musicians, happening to be gifted with more fancy and more hand than their neighbours, were thought infame; as friar Bacon, for superior science, was thought a magician, and Galileo a heretic.

VERA-CRUZ, in Geography, a sea-port of Mexico, in the province of Tlaxcala, with a secure harbour, defended by a fort, upon a rock of a neighbouring island, called St. John d’Alva, in the gulf of Mexico. This is fortified with 350 pieces of cannon; and signals are made from a high tower. This is a place of very great extent, and perhaps one of the most considerable in Spanish America for trade, it being the natural centre of the American treasure, and the magazine of all the merchandise sent from New Spain, or of that transported hither from Europe. It receives a prodigious quantity of East India goods over land from Acapulco, brought from the Philipine Isles. Upon the annual arrival of the flota here from Old Spain, a fair is opened, which lasts many weeks, when this place may be said to be immenely rich. Its situation is unhealthy, from the bog round it, and the barrenness of the soil. It parts the sea in a semicircle, and is inclosed with a single wall or parapet, six feet high and three broad, surmounted by a wooden palisade much decayed. The wall is flanked with fixe feeble battions, on square towers twelve feet high. On the shore to the S.E. and N.W. are two redoubts, with some cannon to defend the port. The houses are well built with stone and lime, and have wooden balconies. The streets are wide, well paved with pebbles, and kept in excellent order. The churches are much decorated with silver; and in the dwelling-houses, the chief Luxury consists of porcelain and other Chinese articles. The principal inhabitants are merchants; but European commerce is mostly carried on at Xalapa. The population is about 7000 or 8000; the inhabitants are generally proud, indolent, and devout; but commerce is well understood, and here are seven or eight houfes, each worth a million of dollars. The women are rarely handsome, and live in retirement; the only amusements being a coffee-houf and procussions, or religious masquerades, the penitents whipping themselves with much bloodshed. A charity of 5000 dollars to marry four poor girls has, as it usual in such cases, reverted to the rich. The harbour of Vera-Cruz might offer anchorage to 30 or even 60 ships of war in four to ten fathoms; but the northerly winds are terrible, and often drive vessels on shore. In the rainy season the marshes on the south are haunted by caymans, or alligators, from seven to eight feet in length, but innocent. The sea-fowl are innumerable, and the mosquitoes very troublesome. The north winds are said to be so violent, that the ladies are excused from going to mass; and these gales sometimes load the walls with sand. In the rainy season the water regularly falls in the night. Earthquakes are frequent. Vera-Cruz having been taken and plundered several times by the Buccaneers, the Spaniards have built forts, and placed sentinels along the coast; their ordinary garrison consisting only of 60 horse and two companies of foot; 180 miles E.S.E. of Mexico. N. lat. 19° 4', W. long. 97° 20'.

VERA-CRUZ, a port in the bay of St. Philip and St. Jago, in Terra Australis del Espirito Santo, discovered by Quito in 1606, and, according to him, capable of containing 5000 ships, with clear foundings of black sand, and water from three feet to 40 fathoms.

VERA-CRUZ, Old, a sea-port of Mexico, in the province of Tlaxcala. This is the port where Cortez landed in 1519: 15 miles N. of Vera-Cruz. This is situated in a valley; and the river is full of caymans, too strong to draw an ox under water. They are fond of the flesh of dogs. N. lat. 19° 20'. W. long. 97° 40'.
VERACUNDALORE, a town of Hindooftan, in the Carnatic; 20 miles S.W. of Bomrauzepollam.

VERAGILA, a small island in the gulf of Venice. N. lat. 44° 11'. E. long. 15° 32'.

VERAGRI, in Ancient Geography, a people of the Alps, in the Pennine valley. Caesar places them between the Nantuates and the Seduni.

VERAGUA, in Geography, a province of Mexico, bounded on the N. by the gulf of Mexico, on the E. by the province of Darien, on the S. by the Pacific ocean, and on the W. by Costa Rica. This coast was first discovered by Columbus, in the year 1503, to whom it was granted, with the title of duke. To the river now called Veragua, he gave the name of "Verdes-aguas," on account of the green colour of its water; or, according to others, because the Indians called it by that name in their language. But however that may be, it is from this river that the province derives its name. In 1528, the captains Gasper d'Espinoza and Diego de Alvaro, renewed the discovery by land; but, being repulsed by prince Urraca, were obliged to content themselves with a settlement in the neighbourhood; and even here the Spaniards were not able to maintain their ground against the frequent incursions of the Indians; so that finding the absolute necessity of a stronger settlement, they built the city Santa Fe, on the spot where it now stands. This province, though geographically belonging to North America, is included within the kingdom or territory of Terra Firma. The country is rugged and mountainous, but abounding with beautiful and excellent woods, and having vales that afford rich patulures. The monkeys found here are small but beautiful, being of a buff-colour, with a white crown; but too delicate to be removed from their native elims. It is said to rain here every day in the year; and the rain is attended with tremendous thunder and lightning, and produces torrents that descend with rapidity and violence from the mountains. Its gold-mines are rich, but little wrought, because every article must be carried on the shoulders of the Indians up the steep mountains. The Doraces, and other savage tribes, live naked by the mountains, on roots and fruits; but several have been converted since the year 1760 by the Franciscans, who have founded some Indian villages. The capital of this province is called by the same name, and also St. Jago de Veragia (which see); it is situated in a warm and moist climate, abounding in maize, yucca, a root of which bread is made, plantains, and cattle, but principally in swine. The natives dye their cotton of a rich and permanent purple, with the juice of a sea-fausl found on the coast of the Pacific, akin to the murex of the ancients; with which, and some gold from the mines, they carry on trade with Panama, and the provinces of the kingdom of Guatamala. Here is an elegant hospital; and fourteen villages are subject to the jurisdiction of this town, which is ruled by a governor.

VERAL, a river of Spain, which runs into the Aragon.

VERALA, in Ancient Geography, a town of Hifpania Citerior, between Calaguris and Trihum.

VERAMALLY, in Geography, a town of Hindooftan, in the Carnatic; 20 miles S. of Trinelpopay.

VERANO AVE, or AVE DE Verano, in Ornithology, the name by which the Portuguese in the Brazil call a large bird of the thrush kind, approaching to the size of a small pigeon, remarkable for its loud noise; and more commonly known by its American name guirapanga.

VERANOCA, in Ancient Geography, a town of Asia, in Phoenicia.

VERAPATCHY, in Geography, a town of Hindooftan, in the Myfore; 20 miles W.N.W. of Dindigul.

VERA-PAZ, a province of Mexico, in the domain of Guatamala, bounded on the N. by the province of Chipa, on the E. by the bay and province of Honduras, on the S. by Guatamala, and on the W. by Soconusco; about 120 miles in length, and 74 in breadth. In one part of the country the air is healthy, in the other not. The country is subject to earthquakes, thunder, and nine months' rainfall. The foil is mountainous, yielding little corn, but abounding in forests of cedar, &c. in which are many wild beasts. The principal commodities are drugs, cocoa, cotton, wool, honey, &c.

VERA-PAZ, or COBAN, a town of Mexico, and capital of the province of Vera-Paz, situated on a river which runs to the bay of Honduras; 660 miles S.E. of Mexico. N. lat. 15° 50'. W. long. 91° 14'.

VERATO, a town of Naples, in the province of Otranto; 4 miles S. of Alessano.

VERATRM, in Botany, which derive from veræ atrum, truly black, because the root is, externally at least, of that colour; may mix or be left among those ancient names whose origin is unknown. It occurs in Lucretius and Pliny, indicating some very active or poisonous plant; and is generally supposed synonymous with the Aconitum Alpinum of Dioscorides, itself rather doubtful, and whose particular designation is a contradiction to the above etymology. Whatever difficulties may attend the determination of the ancient Veratum, this name is now universally applied to the genus we are about to describe, one of whose original species having nearly white, and the other as nearly black, flowers, the English appellations, of White and Black Helbroe, suit them so well, as to efface all memory of old uncertainties.—Linn. Gen. 540. Schreb. 715, Willd. Sp. Pl. v. 4. 895. Mart. Mill. Dict. v. 4. Artt. Hort. Kew. v. 5. 425. Pursh 242. Jaff. 47. Tourn. t. 145. Lam. Marck Illutr. t. 543. Gartn. t. 18.—Clais and order, Polygama Monocora, or more properly Hexandra Trigyna. Nat. Ord. Coronaria, Linn. Junci. Jaff. Melanbach, Brown.

Gen. Ch. Cal. none, unleas the corolla be taken for fuch. Cor. Petals fix, elliptic-oblong, sessile, thinner at the margin towards the base, and finely ferrated or fringed in that part, permanent. Stam. Filaments fix, inserted into the base of the petals,awl-shaped, converging round the germen, spreading at the summit; anthers quadrangular, veratifoliate, attached by the back. Pijf. Germs three, superior, oblong, compressed, erect, combined, terminating in three very short styles, with simple spreading stigmas. Peric. Capsules three, oblong, erect, compressed, of one cell and one valve, burfting at their inner margins by which they are originally connected. Seeds few, obliquely imbricated, inserted into each margin of the capsule, oblong, compressed, winged at each end; the wing at the lower part rounded. Several flowers, on the same plant, have only flight rudiments of a pilil.

Mal. This genus has been thought too near Melan— thium, see that article. The capsules of the latter are fingle, of three cells, and in some species the cells burft externally, but this is not the case with M. floribum, whose cells burft at the inner angle only. The subject wants revision. The habit of Melan-thium, for the most part an Afri- can genus, is very unlike Veratum, the leaves being slender, and inflor- ence more simple. The corolla is more coloured, with elongated claws; and though permanent, has less of the coriaceous nature of a calyx. Helonias, (see that ar-
V. album. White Veratrum, or Common White Hellebore. Linn. Sp. Pl. 1479. Wild. n. 1. Ait. n. 1. Jacq. Auct. t. 335. Fl. Dan. t. 1120. Mill. Ic. t. 271. Mill. Illustr. t. 98. Woody. Med. Bot. t. 100. (Helleborus albus; Ger. Em. 440. f. 1.)—Panicle three-compound. Petals ascending, elliptical.—Native of alpine meadows in most parts of Europe, from Norway to Greece; but not of Britain. It is, of course, a hardy perennial in our gardens, where it has been cultivated out of mind, flowering from June to August. The root is tuberculous, black on the outside, with long, fimbriate, white, cylindrical fibres. Stem from two to five feet high, flat, erect, fimbriate, leafy, terminating in a large, branching, downy panicle, of innumerable greenish-white flowers, with little or no scent, an inch broad, whose petals when in full perfection spread horizontally, but in fading return to their original ascending posture, becoming green, leafy, and coriaceous. The leaves are large, elliptical, entire, with many ribs, smooth, of a fine green; the uppermost becoming oblong or lanceolate bracts. Each partial flower-fall is also accompanied by an elliptical-lanceolate downy bract, various in length. This flatly plant, accompanied by Gentiana lutea, makes a magnificent appearance in rich pastures on the Alps of Switzerland and Savoy, where they both grow more luxuriantly than in gardens.—Mr. Sieber of Prague has sent us from the Alps of Austria, under the name of "V. viride Bernhards," what seems a greenier-flowered variety of the album, and different from the following; but it is extremely difficult to decide on this point, without seeing the plants alive.

2. V. viride. Green Veratrum. Ait. n. 2. Wild. n. 2. Pursh n. 1. Bigelow Bolt. 246. (V. album; Michaux Boreal.-Amer. v. 2. 249. Heloniæ viridis; Curt. Mag. t. 1096.)—Spikes panicled, dense, cylindrical. Petals ascending, elliptical.—In swamps and on mountain bogs, from Canada to Carolina, flowering in July. A flately plant, from three to six feet high. Pursh. Dr. Bigelow, in his Flora Boreali-Americana, says this plant, not unfrequent in meadows and swamps about Boston, is called Poke root, or Swamp Hellebore. It was cultivated in England by Peter Collinson, in 1742. The foliage and habit are like the preceding, but the panicle is larger and greener; its branches longer and more cylindrical, spikèd, not racemose, each flower being nearly or quite sessile. The petals are broader; their margins thickened and mealy about the base.

3. V. nigrum. Dark Veratrum. Linn. Sp. Pl. 1479. Wild. n. 3. Ait. n. 4. Jacq. Auct. t. 336. Curt. Mag. t. 963. (Helleborus albus; Ger. Em. 440. f. 2.)—Clusters panicked, dense, cylindrical. Petals ovate, widely spreading; at length reflexed.—Native of dry mountainous situations, in Siberia, Hungary, Austria and Greece, flowering in July. Perfectly hardy in our gardens, where it blooms early and increases without care. Provided the soil be dry. It agrees with the first species in habit and leaves, but is rather taller, and is very remarkable for the dark purplish-brown, almost black, hue of its flowers, which exhale a faint caddy-vew scent. They compose long, cylindrical, sessile clavures, assembled into a long panicle, accompanied by narrow flat-strapèd bractes in the lower part. Each flower is but half as broad as those of V. album, and the petals turn backward as they fade, becoming finally of a dull green.

4. V. virginicum. Virginian Veratrum. Ait. n. 5. (Melanthium virginicum; Linn. Sp. Pl. 483. Wildl. Sp. Pl. v. 2. 266. Pursh 240. Helonia virginica; Curt. Mag. t. 965. Aphiodelo allia floridana, ramofo cane, floribus ornithogali oblofeitis; Pluk. Amath. 40. t. 434. f. 8.)—Clusters panicked, loose. Petals elliptical, spreading, with two spots at the base; hairy at the back.—In low grounds, amongst luxuriant herbage, from New York to Carolina, flowering in June and July, perennial. Rather scarce in gardens, though tolerably hardy. The stem is from three to five feet high, downy. Leaves linear-lanceolate, folded, ribbed, pointed. Panicle pyramidal, of numerous, lowely racemose, many-flowered branches, whose partial flalks are about half as long again as the petals. Flowers green, with two brown spots on each petal. After being expanded for some time, they turn to a red-brown.

5. V. parviflorum. Small-flowered Veratrum. Michaux Boreal.-Amer. v. 2. 250. Wildl. n. 4. Ait. n. 5. Pursh n. 2.—"Clusters panicked, with slender branches. Petals oval-lanceolate, acute at each end. Leaves elliptical, flat, smooth."—On high mountains in Carolina, flowering in July. Flowers small, green. Root perennial. Pursh. The leaves are like those of a Veratrum, but not so much furrowed, or plaited. Petals without glands. Inflorescence of that of a Melanthium. Michaux. We have seen no specimen nor figure, neither of this nor the following.

7. V. Sabadilla. Cauic Veratrum, or Indian Caufic. Barley. Retz. Obs. fae. 1. 31. n. 107. Wildl. n. 5. (Cevadilla; Dale Pharmac. 286. Hordeum cauicum; Bauh. Pin. 23. Theatr. 467, with a probably fictitious figure. Ytscevumpatii, fett Canis interjector, vel Hordeolum; Hern. Mex. 307, with an apparently authentic figure.)—Leaves linear-lanceolate, ribbed. Clustor simple, dense, folitary, terminal.—Native of the colder regions of Mexico. The leaves appear to be all nearly radical. Stem solitary, simple, erect, almost naked, three flans high. Clustor erect, cylindrical, a flan long, nearly or quite simple. Flowers turned to one side, of a very dark purple. Petals ovate.—Retzius, who first introduced this plant into a scientific botanical work, found a specimen of the flowers, imported along with the seeds, in a druggist's shop. They answered to the character of a genuine Veratrum, as might be expected from the seeds and capsules, which we have occasionally met with, and whose qualities are analogous to those of V. album. But the learned professor never thought of tracing out the synonyms, or searching for any figures, of this little-known plant; which defect we have endeavoured to supply. For the medical properties of the seeds in question, see CEVADILLA.

For V. luteum, Linn. Sp. Pl. 1479. Wildl. n. 6, see HELONIAS, n. 3.

Veratrum, in Gardening, contains plants of the hardy, herbaceous, perennial kind, among which the species cultivated are, the white-flowered veratrum, or white hellebore (V. album); the dark-flowered veratrum (V. nigrum); and the yellow-flowered veratrum (V. luteum).

The first has the flalks three or four feet high, and branching out on every side almost their whole length; the branches and principal flalk being terminated by spikes of flowers set very close together, which are of a greenish-whitc or herbaceous colour, and appear in July.

The second has the flalks rising higher, but the flowers are of a dark-red colour, which appear almost a month sooner.

The third has a large tubercular root with a single flalk, about a foot high, having the flowers produced at the top, in a single thick clove spike, which are small, and of a yellowish-white colour, appearing in June.
Method of Culture.—All these plants may be increased by seed and parting the roots.

The feed should be sown in the autumn or early spring, upon a bed or border of light earth, or in a box filled with the same port of mould. When the plants are come up in the spring, keep them clear from weeds, and refreshed with water occasionally when the season is hot and dry; and in the following autumn, when the leaves decay, take them up carefully without injuring the roots, and plant them out about half a foot square in a fresh bed of light mould; and when they have remained in it till fit for flowering, they should be removed into the borders, clumps, or other parts.

This is, however, a tedious method, as they seldom flower in less than four years; therefore the root method is most likely to succeed in the first spring, when the leaves decay, and be planted out in a light, fresh, rich mould where they are to grow; they should not be removed oftener than once in about four years. The roots should not be parted too small.

These plants have a fine effect in the middle of large borders, clumps, and other similar situations, in pleasure grounds and other places by the singularity of their large furrowed leaves, and their different modes of flowering.

The first sort is much cultivated as a medicinal plant for the use of its root, as well as the black sort occasionally; in which intention the plants should be set out in beds or borders in any common parts of the ground.

Veratrum, in the Materia Medica. See Hellebore.

Mr. James Moore has suggested that a vinous infusion of the root of the veratrum album, or white hellebore, constitutes the active ingredient in the eau médicinale d’Huffon. Mr. Moore gives the following preparation: take of white hellebore-root, eight ounces; white wine, two pints and a half. The root is to be cut in thin slices, and infused for ten days, occasionally shaking the bottle. Let the infusion be then filtered through paper.

The dose of the mixture, in cafes of gout, may be from one fluid-drachm to three fluid-drachms.

Verb, in Grammar, a word serving to express what we affirm of any subject, or attribute to it; or, it is that part of speech, by which one thing is attributed to another, as to its subject; as the words is, underlands, bears, believes, & c.

This is, in other words, the definition of a verb adopted by Dr. Prießløy in his Grammar. But this definition seems to include not only verbs, but likewise all adjectives, and abstract nouns signifying qualities; for when we say " God is good," or " Goodness belongs to God," do not the words " good" and " goodness" express what is affirmed of or attributed to the Deity? But if in this definition it is merely affirmed, that the essence of the verb conveys in affirmation, it might have been expressed with greater precision, thus: " a verb is a word affirming something of, or attributing something to, a thing." It is, says Dr. Blair, the affirmation that seems to be that which chiefly distinguishes the verb from the other parts of speech, and gives it its most copious power. Hence there can be no sentence, or complete proposition, without a verb either expressed or implied; for whenever we speak, we always mean to assert, that something is or is not; and the word which carries this affirmation, or affirmation, is a verb. This ingenious writer, however, seems to have improperly included time as one of the three things implied in all verbs, adding this to the attribute of some substantive, and an affirmation concerning that attribute. The definition of Dr. Beattie seems to be more objectionable. He defines a verb to be " a word necessary in every sentence, signifying the affirmation of some attribute, together with the designation of time, number, and person." According to this definition, neither infinitive moods, nor gerunds, nor participles, nor verbs are verbs; for they neither contain an affirmation, nor signify time, nor are limited either to number or person. If affirmation, which we conceive to be the case, be essential to verbs, it is possible to form a tolerably copious language with only one verb in it; for infinitives, participles, adjectives, &c. may be so united to nouns by the copula, or verb is, alone, as to express almost any idea which we can have occasion to communicate. But if the circumstances of time, person, and number, be essential to verbs, it is more than probable that languages may subsist without verbs, which have not a single verb in them. And in this case Dr. Beattie cannot sufficiently maintain, as he affirms, that a verb is " a word necessary in every sentence." In the Malay language, e.g. which is held in high estimation, and which has wide extent in the East Indies, the verb admits of no modification whatever, on account, either of person, tense, or voice; in all these respects, the personal pronouns only, with particles prefixed, determine the sense.

The verb is thus called of the Latin verbum, word, by way of eminence; as being the principal word of a sentence. Accordingly verbs, as Dr. Adam Smith observes, must have been coeval with the first attempts towards the formation of language. No affirmation can be expressed without the allusion of some verb. This writer suggests, that the radical verb, or the first form of it, in most languages, would be what we now call the imperfect verb: as " it rains," and the like: as this is the simplest form of the verb, and merely affirms the existence of an event, or of a state of things. By degrees, after pronouns were invented, such verbs became personal, and were branched out into all the varieties of tenses and moods. On this subject, see Verb, Substantive, infra.

The common definition given by grammarians is, that the verb is a word which betokens being, doing, or suffering. This is the definition of the learned Bishop Lowth, and it includes nothing more than what is essential: so that it is equally applicable to the verb in all languages, in all its various forms, comprehending not only infinitives and participles, but likewise gerunds and participles. If it is in any respect defective, it is because it does not in all cases sufficiently distinguish verbs from verbal nouns. Infinitives and participles, gerunds and participles (see each in its place), not only signify actions, but govern the cases of nouns and pronouns in the same manner with the verbs, and therefore should be comprehended under the name of verbs. But those verbal nouns which do not govern accussative cases have not the fame prepositions; for they have not the regimen of verbs, but of substantives, and consequently more properly belong to that class.

To conceive the origin and office of verbs, it may be observed, that the judgment we make of anything, as when I say the earth is round, necessarily includes the perception of the fact; the first, called the subject, is the thing we affirm of, e.g. earth. The second, called the attribute, is the thing affirmed, e.g. round. The third, is, connects those two terms together, and expresses the action of the mind, affirming the attribute of the subject.

This last is what we properly call the verb; and which some of our later grammarians, particularly the Port Royalists, choose to call by a more significative word, affirmation. The reason is, that its principal use is to signify affirmation; that is, to shew the discourse in which that word is used, is the discourse of a man who does not only conceive things, but judges and affirms somewhat of them.
By this circumstance, a verb is distinguished from nouns, which also signify an affirmation, as affirms: affirmatio: those only signify affirmation, as that, by a reflection of the mind, is rendered an object of thought: so that they do not shew, that the person who utters them affirms, but only that he conceives an affirmation.

Though the principal use of verbs be to signify affirmation or assertion, they also serve to express the other motions of the soul; as to define, pray, command, &c.; but this they only do, by changing the mood, or inflexion.

Here, we only consider the verb in its primary significations, which is that it has in the indicative mood. On this footing, the verb should have no other use, but to mark the connection which we make in the mind, between the two terms of a proposition; but the verb齿轮, to be, is the only one that has retained this simplicity: nor, if strictness, has this retained it, but in the third person, as齿轮 is.

In effect, men being naturally inclined to shorten their expressions, to the affirmation they have almost always added other significations in the same word: thus, e.g. they add that of some attribute, so as that two words make a proposition: as in Petrus vivit, Peter lives: where vivit includes both the attribute and affirmation: it being the same thing to say Peter lives, as that Peter is living. And hence the great variety of verbs in every language: for if people had been contented to give the verb its general significations, without any additional attribute, each language would only have needed one verb, viz. the verb substantive齿轮, is.

Again, on some occasions, they also superadd the subject of the proposition, as sum homo, I am a man; or vivit, I live: and hence the diversity of persons in verbs.

Again, we also add to the verb, a relation to the time, with regard to which we affirm: so that one single word, as conatus, signifies that I attribute to the person I speak the action of floating, not for the present time, but for the past: and hence the great diversity of tenses in many verbs.

The diversity of these significations, or additions in the same word, has perplexed and deceived many of our best authors, in the nature of a verb; and has led them to consider it, not according to what is essential to it, which is to affirm: but according to some of these incidental relations.

Thus, Aristotle, taking up with the third of those additional significations, defines verb to be vox significans cum tempore; a word signifying something with time.

Others, as Buxtorf, adding the second relation, define it, vox flexibus cum tempore et persa; a word admitting of divers inflexions, in respect of time and person.

Others, taking up with the first of the additional significations, which is that of the attribute, and considering that the attributes men ordinarily add to the affirmation, were actions and passions, have supposited the essence of a verb to consist in signifying actions or passions.

Lastly, Scaliger imagined he had made a great discovery in his book of the Principles of the Latin Tongue, in laying, that the distinction of things into permanentes, and fluentes, into what remain, and what pass away, is the proper source of the distinction between nouns and verbs: the first being to signify what remains, and the second what passes.

But from what we have said, it is easy to perceive, that these definitions are all false: and that the only true definition is vox significans affirmationem: this definition includes all that is essential to the verb: but if one would likewise include its principal accidents, one might define it, vox significans affirmationem, cum definitione persena, et temporis: a word which signifies an affirmation, with a designation of person, number, and tense; which is what properly agrees to the verb substantive齿轮.

For as to other verbs, considered as becoming different by the union of certain attributes, one may define them thus: vox significans affirmationem alterius attributi, cum significacione persena, numeri, et temporis: a word which expresses the affirmation of some attribute, with a designation of person, number, and time.

Verbs, according to Mr. Harris, are those attributes, which have a complex power of denoting both an attribute and an affirmation: those which take the attribute alone without the affirmation are participles; and all the other attributes are included under the general name of adjectives. And as some attributes have their essence in motion, e.g. to walk, to live, &c. others in the privation of motion, e.g. to die, &c. and others again in subjects, which have nothing to do with either motion or its privation, as great and little, white and black, &c. these last are adjectives, and adjectives which denote motion or its privation are either verbs or participles. And motions and their privation, comprehended under the general term energy, imply time as their concomitant, and hence, he says, verbs which denote them, come to denote time also. See Tense. See also Mood.

Every energy has a reference, says this ingenious writer, to some energizing subsistence, and is conversant about some subject, and hence he derives the distinction between verbs active and passive: and as every energy respects an energizer, or a passive subject, hence appears the reason why every verb, whether active or passive, has in language a reference to some noun for its nominative case. When among the infinite subjects, to which the energy refers, that happens to occur, which is the energizer also, as Brutus loved bimself, loved himself, &c. in such case the energy hath to the same subject a double relation, both active and passive: and this gave rise among the Greeks to that species of verbs, called verbs middle: but in other languages, the verb still retains its active form, and the passive subject (fe or bifelf) is expressed like other auxiliatives. Again, in some verbs, it happens that the energy always keeps within the energizer, and never passes out to any foreign subject, because the energizer and the passive subject are united in the same person; and then we obtain that species of verbs, called by grammarians verbs neuter, as if they were void both of action and passion, though they may rather be said to imply both. Of the above species of verbs, the middle cannot be called necessary, because most languages have done without it: those remaining are, therefore, the active, the passive, and the neuter, which seem essential to all languages whatever. Mr. Harris observes, that though the greater part of verbs denotes attributes of energy and motion; there are some which appear to denote nothing more than a mere simple adjective, joined to an affirmation, as ἐγείρει in Greek, equalled in English, alio and tunc in Latin; and there are also verbs, which are formed out of nouns, or in which the substantive is converted into an attributive. There are other superposed affections of verbs, besides moods and tenses, such as number and person. But these are, in fact, the properties not of attributes, but of substantives. Hermes, chap. vii. viii. and ix.

Verbs are variously divided: with respect to a subject or object, they are divided into actives, passives, or neuters, &c.; with respect to their construction, into transitive and intransitive; with respect to their formation or inflexions, into regular and irregular, personal and impersonal: their auxiliary, subjunctive, &c. See Language, Grammar, and the subjacent articles.
VERB.

**Verb Active**, is a verb which expresses an action that falls on another subject, or object. It is called also 
*transitive*, because the action paffeth over to the object, or hath an effect upon some other thing. See **Active**.

**Verb Passive**, is that which expresses a passion; or which receives the action of some agent, and necessarily implies an object acted upon, and an agent by which it is acted upon: it is conjugated, in the modern tongues, with the auxiliary verb *I am, je suis, je sono, &c.*

Some do not allow of any verbs passive in the modern language; the reason is, what we call passive is nothing but the participle of the verb, joined with the auxiliary verb, *to be*; whereas the verbs passive of the Latin, &c. have their particular terminations. See **Passive**.

**Verb Neuter**, is that which signifies an action that has no particular object on which to fall; but which, of itself, takes up the whole idea of the action: or a verb neuter expresses being, or a state or condition of being; when the agent and the object acted upon coincide: as, *I sleep, thou waknest, he frowns, we walk, you run, they fland.*

The Latins call them *neuters*, because they are neither active nor passive: though they have the force and significations of both; as, *I languijhe, signifies as much as, I am languijbing; I obey, as much as, I exercise obedience, &c.* only that they have no regimen to particularize this significations. The verb neuter is called *intrative*; because the effect is confined within the agent, and doth not pass over to any object.

The difference between verbs absolutely neuter, as, *to sleep, and verbs active intrative, as, to walk, though founded in nature and truth, is of little use in grammar; the construction of both is the same. Lowth's Gram. p. 62.

Of these verbs, there are some which form their tenses by the auxiliary verb *have*; as, *I have slept, you have run.* These, grammarians call *neuter active*.

Others there are, which form their compound parts by the auxiliary verb *to be*; as, *I am come, I am arrived.* These are called *neuters passive*.

The neuter verb is varied like the active; but, having somewhat of the nature of the passive, admits in many instances of the passive form, retaining still the neuter significations: chiefly in such verbs as signify some sort of motion, or change of place or condition; as, *I am come, I was gone,* &c.

In English, many verbs are used both in an active and neuter significations, the construction only determining of which kind they are.

**Verb Sublative**, is that which expresses the being, or subsistence, which the mind forms to itself, or supposes in the object; whether it be there, or not as, *I am, thou art.*

Existence, says Mr. Harris, may be considered as an universal genus, to which all things of all kinds are at all times to be referred. The verbs, therefore, which denote it, claim precedence of all others, as being essential to the very being of every proposition in which they may be found, either express, or by implication; express, as when we say, *the sun is bright*; by implication, as when we say, *the sun rises*, which means, when resolved, *the sun is rising.* The verbs *is, groweth, becometh, eft, fit, etept, ete, *πη, πης, πησ, πησαι, are all used to express this general genus; and are called by the Latins *verbs sublantes*, and by the Greeks *μετορα, σπερμα, verbs of existence*, a name more apt, as being of greater latitude, and comprehending equally as well attribute as subsistence. The principal of these verbs is the verb *is, eft, it.* All existence is either absolute, as when we say, *B is*; or qualified, as when we say, *B is an animal, B is black,* &c. And with respect to this difference, the verb, *is, can by itself express absolute existence, but never the qualified, without subjoining the particular form; consequently, when *is* only serves to subjoin some such form, it has little more force than that of a mere affirmation. Under the same character, it becomes a latent part in every other verb, by expressing that affirmation, which is one of their essentials: e.g. *riseth means is rising, &c.* Moreover, as to existence in general, it is either mutable, as in the objects of affection; or immutable, as in the objects of intellection and science. All mutable objects exist in time, and admit the several distinctions of present, past, and future: but immutable objects know no such distinction, but rather stand opposed to all things temporary. And hence refult two different significations of the sublantine verb *is*, as it denotes mutable or immutable being: e.g. *if we say, this orange is ripe, is meaneth that it existeth fo now at this present, in opposition to past time, when it was green, and to future time, when it will be rotten: but if we say, the diameter of the square is incommensurable with its side, we do not intend by it that it is incommenurable now, having been formerly commensurable, or being to become fo hereafter:* on the contrary, we intend that perfection of existence, to which time and its distinctions are utterly unknown. Under the same meaning, we employ this verb, when we say, *truth is,* or *God is*: the opposition is not of time present to other times, but of necessary existence to all temporary existence whatever. Hermes, p. 88, &c.

In every language, says Dr. Adam Smith, in his "Formation of Languages," annexed to his "Theory of Moral Sentiments," there is a verb, known by the name of the sublantine verb, in Latin, *sum, in English, I am.* This verb, he says, denotes not the existence of any particular event, but existence in general. On this account it is the most abstract and metaphysical of all verbs, and consequently could by no means be a word of early invention. Nevertheless he allows, that it is in every language; and therefore in languages which are in their earliest infancy. Others are of opinion, not without reason, that the verb sublantine, or copula, *is, is not only the most necessary, but the most simple of all verbs, for it contains nothing more than an affirmation, or affirmation, that a thing exists. The idea conveyed by this simple proposition is coeval with thought itself: for what can we think about, unless we think that something is, or exists? This copula, or verb of existence, *is, must appear to be coeval with language itself. But we cannot reasonably infer from hence, that this was the case with respect to any other finite verb. It is probable, that people, in their first attempts to express their ideas by words, would be some time before they invented any other word containing in itself an affirmation or affirmation: for they would not, at a very early period, think of contriving words fo complex in their nature as to include in them both the name of an action and an affirmation.*

An ingenious writer on the subject of verbs (see Pick-bourn's Differtation on the English Verb) conjectures that the first mode of expressing actions or passions would be by participles or verbal nouns; i.e. words signifying the names of the actions or passions they wanted to describe; and these words, connected with their subject by the copula *is* (a word coeval with speech itself), might, in these rude beginnings of language, tolerably well supply the place of verbs; e.g. from observing the operations of nature, such words as *rain or raining, thunder or thundering,* would soon be invented; and, by adding the copula *is,* they would say, *thundering, or thunder, it, or is not; raining, or rain, it,* which, by the rapidity of pronunciation, might in time
time form the verbs rains, thunders, &c. The observation of their own actions, or the actions of the animals around them, would soon increase their stock of ideas, and put them upon contriving suitable expressions for them. Hence might arise such words as these: sleep, or sleeping; fland, or standing; run, or running; bite, or biting; hurt, or hurting: and by joining these to substantives, by means of the copula it, they might form such fentences as these, Lion is sleeping, or perhaps Lion is fland, &c.; which would soon be contracted into Lion sleeps, flands, runs, bites, hurts, &c. Thus our little influated family might become possified of verbs including an attribute and an affirmation in one word.

The next step would probably be a distinction between actions in their progressive and in their finished state; i.e., actions going on in their presence, and perceived by their senses; and such as were ended, and consequently only known to them by memory, or by report, or by their effects: and they might perhaps affix such words as raining, thundering, sleeping, &c. to the former kind of actions; and such as rain'd, thunder'd, slept, &c. to the latter. And by joining the copula is to these words signifying perfect actions, in the same manner in which they had joined it before to the words signifying imperfect ones, and afterwards contracting them into single words, they might soon acquire a verb expressing a finished action and an affirmation in one word. This improvement would probably suggest to them the idea of making such further alterations in, or additions to, their verbs, as would make them significant of all the grand divisions of time.

But still their verbs would have neither person nor number, and would probably remain in that state till the invention of pronouns. But this, requiring some degree of abstraction, would probably not happen very early; for, in their first efforts to express themselves, they would be more likely to say, “Thomas loves William and Henry,” than “I love thee and him.” However, in process of time, pronouns would no doubt be introduced: and they might perhaps make such alterations in their verbs, as to accommodate them to their numbers and persons, though such an accommodation does not seem absolutely necessary. Languages may hereafter exil which do not vary their verbs to express either number or person. And, further, it is possible that there may be languages so constructed as not to admit any variation in their verbs, even to express time: for if the verb only contains, in itself, an assertion and an attribute, the time of it may be fixed by adverbs and other adjuncts. This author concludes that a definition applicable to the verb in all languages, and in all its forms, cannot comprehend in it any thing more than what bishop Lowth has expressed by saying, “A verb is a word signifying to be, to do, or to suffer.”

The copula, or sublitative verb, is, according to this author, is, as we have already stated, the simplest of all verbs; and must necessarily have been contemporary with the first efforts of mankind to express their ideas by words. Without this we cannot unite an adjective to a sublitative, or affirm that any thing is good or bad, or poseffes any quality whatever, or even exisits. But this is the only verb, containing an affirmation, which is fo perfectly simple in its nature as not to comprehend, at least, two ideas, which may be easily separated, nay which must necessarily be separated, in the operations of the mind, whenever it endeavours to express them. Plures, it rains, or is raining, comprehends the idea which the mind forms of that operation of nature which we call rain or raining, and likewise an affirmation of the judgment which the mind forms concerning its present existence; and therefore cannot be expressed more simply and naturally than by is raining, or rain is, which is easily contracted into, rains.

**VERBS, Auxiliary, or Helping, are those which serve in conjugating active and passive verbs; such are, I am, I have &c.**

The auxiliary verbs are like prepositions, words of a very general and abstract nature. They imply the different modifications of simple existence, considered alone, and without reference to any particular thing. In the early state of speech, the import of them would be incorporated with every particular verb in its tenses and moods, long before words were invented for denoting such abstract conceptions of existence, alone and by themselves. But after those auxiliary verbs, in the progress of language, came to be invented and known, and to have tenses and moods annexed to them, like other verbs; it was found, that as they carried in their nature the force of that affirmation which distinguishes the verb, they might, by being joined with the participle which gives the meaning of the verb, supply the place of most of the moods and tenses.

The abbot de Dangeau distinguishes all verbs into two general kinds; auxiliary verbs, and verbs which make use of auxiliaries.

This distinction some may tax as not very just: in regard auxiliary verbs sometimes make use of auxiliaries themselves: but this does not destroy the division; it only shews, that the auxiliary verb has two formalities, or two different qualities, under which it is to be considered: in virtue whereof, it constitutes, as it were, two forts of verbs.

The verbs which make use of auxiliaries, he divides into active, neuter, and pronominal. Verbs neuter, he farther distinguishes into neuters active and neuters passive. Pronominals he distinguishes into identics, reciprocal, neutrized, and perfected. But several of these are peculiar to the French language. See **Auxiliary Verbs.**

When an auxiliary is joined to the verb, the auxiliary goes through all the variations of person and number; and the verb itself continues invariably the same. When there are two or more auxiliaries joined to the verb, the first of them only is varied according to person and number. The auxiliary must admits of no variation.

**VERBS, Regular, are those which are conjugated after forme one manner, rule, or analogy.**

**VERBS, Irregular, or Anomalous, are those which have something singular in the terminations or formations of their tenses. See **Anomalous Verbs.**

The formation of verbs in English, both regular and irregular, is derived from the Saxon. The irregular verbs in English are all monosyllables, unless compounded; and they are for the most part the same words which are irregular verbs in the Saxon. The first class of irregulars comprehends those that are become so from some kind of contraction: thus, some verbs ending in dor or t have the present, the past time, and the participle perfect and passive, all alike, without any variation; as, eat, hurt, end, &c. which are contractions from beaten, hurled, ended, &c., because of the disagreeable sound of the syllable of after dor or t. Others in the past time and participle perfect and passive, vary a little from the present, by shortening the doubleght, or changing the d into t: as, lead, led; move, mov'd, move, &c. Others not ending in dor or t are formed by contraction: as, burn, stood, for based; set, set, for possest, &c. The following, beside the contraction, change also the vowel: pull, pull'd; rent, rent'd; catch, catch'd.

The second class of irregulars are those that end in ge, both in the past time and participle, and change the vowel or diphthong into ou or ou: they are taken from the Saxen, in which the termination is eou: ang, hung, bough, bow, bought; feow,
VER 

VER

The third class of irregulars form the past time by changing the vowel or diphthong of the present; and the participle perfect and passive, by adding the termination en: these also derive their formation from the Saxon: such are, full, fell, fallen; smoke, smoked, smoked; draw, drew, drawn; play, played, player.

When en follows a vowel or liquid, the e is dropped. Some verbs, which change i short into a or u, and i long into o, have dropped the termination en in the participle; as, begin, began, begun; sing, sang, or song; &c. To this third class belong the defective verbs, be, been; go, gone, &c.

The whole number of verbs in the English language, regular and irregular, simple and compounded, taken together, is about four thousand three hundred. See in Dr. Ward's Essays on the English Language the catalogue of English verbs. The whole number of irregular verbs, including the defective, is about one hundred and seventy-seven. Lowth's Gram. p. 84. See conjugation.

Verbs, defective, are those which are not only for the most part irregular, but are also wanting in some of their parts. Such are the auxiliary verbs, most of which are of this number. They are in use only in some of their tenses and moods; and some of them are a composition of tenses of several defective verbs having the same significations.

Verbs Inchoative. See Inchoative.

Verbs Imperfessional. See Imperfessional.

There are also reduplicative verbs; as, refused, recall, &c.; and frequentative verbs, &c.

Verbs, Transitive. See Transitive, and Verb Active, supra.

For the observations of an ingenious and learned commentator on the origin, nature, distribution, and properties of verbs, we must content ourselves with referring to the article Grammar. It will be found that his sentiments differ in a variety of respects from those of many approved and popular writers, above stated: and we therefore prefer submitting them in the language of the author to the judgment of the philological reader, without any abridgment, and without any recapitulation, which would encroach too much on the limits to which we are confined. On this subject, see Language.

Verbal, something that belongs to verbs, or even to words spoken with the mouth.

Verbal nouns, are those formed from verbs. See In- 

Finitive.

A verbal contract, is that made merely by word of mouth, in opposition to that made in writing.

Verbal Accident. See Accident.

Verban., in Geography, a department of Italy, constituted of part of the duchy of Milan, situated on the side of lake Major, anciently called Verbanus Lacus, and the bailiwicks ceded by the Swifs. It contains 166,842 inhabitants, who elect twelve deputies. Varecio is the capital.

Verbanus, in Ancient Geography, a lake of Gallia Transpadana; its northern part was in Rhetia, and its southern part in Gaul.

Verbas, in Geography, a river of Bofnia, which runs into the Save; 25 miles N.N.E. of Banjaluka.

Verbasculum, in Botany, the diminutive of Verbascum, perhaps from some similarity of colour and aphis, which may be traced in the Primrose and Cowslip. Bauh. Pin. 241. This is precisely synomous with Primula; see that article.

Gen. Ch. Cal. Perianth inferior, of one leaf, small, permanent, in five deep, erect, acute, nearly equal, segments. Cor. of one petal, wheel-shaped, unequal; tube very short; limb spreading, in five deep rounded segments. Stam. Filaments five, awl-shaped, unequal, distant, declining, woolly, shorter than the corolla, inserted into its base; anthers compressed, erect, more or less kidney-shaped, bearded; Profil. Gement inferior, roundish; style thread-shaped, slightly swelling upwards, declining, rather longer than the flaments; Stigma obtuse. Peric. Capsule roundish-ovate, or ovate-oblung, slightly compressed, of two cells and two valves, burbling in the upper part, the valves sometimes splitting half way down; partition double, from the inflexed parallel margins of the valves, but often incomplete. Recept. ovate or globular, central, connected at each side, in an early flat at leaf, with the valves. Seeds numerous, minute, angular, dotted, inserted into the receptacle.

Obs. There is a great space between the inner edges of the inflexed valves and the central receptacle, in V. pulv- erulentum and some other species, that the ripe capsule is literally of but one common cell, though originally of two. Hence arose an error in Engl. Bot. p. 58, 59, which is corrected at p. 487 of the same work. Celsia (see that article) differs from this genus in having four flaments only, two long and two short. Professor Schrader, in the first part of an excellent monograph on Verbascum, published at Gottingen in 1813, p. 14, affirms that this difference is very constant and invariable, and therefore he is not disposed to concur with those botanists who combine these two genera. We heartily attend to this determination. With regard to the new genus of Ranonia, founded, if we mistake not, on V. Myconi, and distinguished by having a capsule of one cell, with two lateral linear receptacles; we must suspend our judgment till we can examine into that character, but the habit of the plant, and its oblong heart-shaped two-celled anthers, indicate a very distinct genus.

The species of Verbascum are among the most uncertain of any well-known genus. They are more than commonly variable in the colour and size of their flowers, and appear to be very subject to crofts inpregnation. Hence we are led to mistrust some reputed species, described even by the ablest writers. The production of several mere ones has been traced and recorded, and we have observed others. Professor Schrader indeed has long cultivated and studied what he has described, and his accuracy is indisputable. We shall give his new species, on his own authority, and we shall profit by his remarks in the general characters here prefixed to the particular descriptions.

The root is generally biennial, rarely perennial, its form tapering. Stem generally solitary, from a foot and a half to four or eight feet in height, erect, sometimes peculiarly stiff and straight, rarely a little zigzag, leafy, in several influences.
flances alternately branched, many-flowered, panicled, with racemose filacts; in V. Mycota only altogether wanting. Leaves all radical the first year, subequently all cauline: stalked, fleshy, or decurrent; always alternate, simple, oblong; undivided, lobed or pinnatifid; singly or doubly cre- nate or toothed, rarely entire; generally covered with dense, white, hairy or flary, or more and deciduous, woollline; sometimes nearly smooth. Flowers racemose, generally aggregate, crowded, and very numerous; mostly yellow, rarely yellowish-white, or, purple, or browm. Brevicaps. mostly ovate, or lanceolate, pointed, of two orders, external and internal. The whole genus is nearly, if not entirely, European, the species found in America, except perhaps V. Claytoni of Pursh and Michaux, having been apparently introduced from this quarter of the world. The Levant produces many fine ones, not well known to Linnaeus.

Sec. 1. Leaves deciduous.

1. V. Thapsius. Great Mullein; or High Taper. Linn. Sp. Pl. 252. Wildl. n. 1. Schrad. n. 1. Pursh n. 1. Pl. Brit. n. 1. Engl. Bot. t. 549. Fl. Dan. t. 634. (Thapsus barbitus; Ger. Em. 777. Φάππος, λιγνὸν αἰφένα; Dioec. book 4. chap. 104.)—Leaves decurrent, crenate, white, on both sides. Stem fleshy. Clusters dense. Flowers almost fleshy. —Found frequent throughout Europe, on banks and waste ground, flowering in July and August; very common in Greece. Mr. Pursh observes that, though common in America, this plant was probably introduced from Europe; nevertheless it spurs up abundantly in the most remote parts of the country, in fields newly cleared and burnt. The root is biennial. Stem from three to five feet high, erect like a staff, fleshy, winged with decurrent acute leaves, which are clothed with white entangled flary wool, like cloth or flannel. Flowers very numerous, large, of a bright golden-yellow, with orange-coloured hairy flamin, and roundish red anthers. Mr. Robbon of Darlington communicated to Dr. Withering a mule plant, produced under his own eyes, from this species imported by V. myrtum. Mr. D. Turner found a corresponding specime, now before us, at Barton, near Swaffham, Norfolk. The leaves are but slightly decurrent. Spike elongated and slender. The leaves of V. Thapsius, about a handfhaul boiled in a pint of milk, sweetened with sugar, strained, and the milk taken at bed-time, are useful in coughs, and more especially service- able in allaying the irritation of the piles. V. pulex has the same qualities. —V. thapsiformis, Schrad. n. 2. seems fearely more than a variety with a larger corolla, and two of the anthers oblong, instead of their being all round.

2. V. cripifolius. Thick-leaved Mullein. Schrad. n. 3. "Hoffmannelg and Link Lith. v. 1. 213. t. 26."—Leaves decurrent, obtuse ly crenate, densely woolly; the upper ones rather acute. Clusters dense. Flowers all- mott fesitles. Filaments smooth. Two of the anthers oblong.—Found in sandy ground in Portugal. The smooth filaments afford the chief distinction between this plant and the last, at least its variety called thapsiformis. Experience must shew, by cultivation, whether this be permanent.

3. V. cripfolidw. Pointed-leaved Mullein. Schrad. n. 4. t. 1. f. 1. (V. Thapsius; Ebrh. Pl. Off. n. 111.)—Leaves decurrent, crenate, woolly on both sides; the upper ones pointed. Cluster somewhat interrupted. Two of the anthers oblong.—Found in mountainous woods near Vienna. Schott. Near Uphal. Ebrhart. This Dr. Schrader mentions as the V. Thapsius of the Vienna botanists, agreeing in habit with the two foregoing, but the stem is of more humble stature, and more slender. Leaves smaller, less densely woolly; the upper ones taper-pointed. Inflorescence and flowers more like V. filamentosus; the clusters being interrupted, the flowers more flaked, and aggregate in little tufts. Corolla large. Two larger flaments having oblong anthers; and in our speciment from Ehrlhart smooth filaments, though the rest are hairy.

—Found near Naples. Stem two or three feet high, round; at length smooth and brownish. Leaves thickish, soft; their upper surface becoming green and slightly downy, though the under is snow-white. Flowers yellow, in tufts, almost seflile, about the size of V. Thapsius. Filaments clothed with white wool. Schrader. This appears to be really a very distinct species.

5. V. densus. Denfe-flowered Mullein. "Bertol. Pl. Rat. Ital. v. 3. 52." Schrad. n. 4.—Leaves downy; the radical ones lanceolate, elongated, crenate, deeply fer- rated at the base; upper item-leaves pointed, toothed, half-decurrent. Clusters dense. Flowers aggregate, nearly seflile. —Found on the summit of mount Brucciana, between Carrara and Maffi. Stem four or five feet high, angular, clothed with tawny woolllines, especially the upper part. Radical leaves more than eighteen inches long, two or three broad in the middle; green above; woolly hairy beneath; three of the items gradually shorter upward, ovate, pointed, sessile, with a small decurrent wing on each side, more downy all over, especially the uppermost. Clusters very dense, above a foot long. Flowers large, yellow, in tufts on extremely short filacts. Pubescent of the whole plant yellowish or tawny, compofed of branched entangled hairs, and much the most dense in the upper part. Bertoloni.

6. V. thapsoides. Long-spiked Mullein. Schrad. n. 7. t. 5. f. 2. "Hoffmannelg and Link Lith. v. 1. 214, exclud- ing the synonymus."—Leaves finely crenate, downy; radical ones oblong-lanceolate; the rest oblong, acute, half-decurrent. Flowers on short filacts, aggregate, rather crowded. Anthers nearly equal. —Native of Portugal. Perennial. Stem three or four feet high, or more, generally branching at the top into several long, rather slender, tolerably dense clusters of yellow flowers, smaller than V. Thapsius. Schrader. We conceive this to be no other than the Linnaean V. Thapsis; see V. Lychnis.

7. V. maculatum. Great-flowered Mullein. Schrad. n. 8. "Hoffmannelg and Link Lith. v. 1. 215. t. 27."—Leaves finely crenate, downy; radical ones elliptic-oblong, tapering at the base; the rest oblong, acute, half-decurrent. Clusters interrupted, with dilute tufts of flowers. Two of the anthers oblong.—Found by way fides, in the northern part of Portugal. Root topised to be biennial. Stem two or three feet high, erect, fimple, at length smooth and of a purplish-brown. Leaves thick, reticulated with veins beneath; their upper side becoming green and almost naked by age; radical ones flaked, three or four inches long, and half as broad. Flowers large, handfómfe, yellow. Hair of the filaments orange-coloured. Capsule small. Schrader.

ground in the south of Europe, and east of Asia. We gathered it on the ramparts of Pavia; and Dr. Sibthorp at Constantinople. A large biennial species, hoary all over, with denfe, flarry, entangled, woolly hairs. Stem solitary, erect, simple, round, leafy, ending in a long, interrupted, many-flowered, fucculuated stamens, sometimes accompanied at the base with one or more much shorter ones. Radical leaves, as well as those on the lower part of the stem, four inches or more in length, flaked, broadly ovate, bl untifh, obtusely crenate, thick, ruged, reticulated with copious veins, each tapering at the base into a winged footstalk: the upper ones gradually smaller, pointed, fucculent; heart-shaped at the base, clasping the stem, and somewhat decurrent; diminishing into taper-pointed bracteas, which project further than their respective tufts of flowers. Flowers large and handsome, of a golden-yellow, about five in each tuft, accompanied by small, lanceolate, partial bracteas. Partial flasks shorter than the calyx, which is smooth internally. Stamens purple, either all denfely hairy, with yellow, nearly uniform, anthers, or two of them bare or less oblong and imperfect anthers; in which case the respective filaments are less hairy, or quite naked. Germin clothed with very denfe wool, which comes off as the cauleale ripens.

We fearcefly discover any difference between the V. australis of our learned friend, and the phlomoides, of which his description answers exactly to our specimens. The radical leaves of the australis perhaps are larger and more lanceolate, but this can hardly indicate more than a variety. The anthers and filaments are acknowledged to vary in both, and we have found them to do so in phlomoides.

9. V. condensatum. Denfe-flowered Round-leaved Mullein. Schrad. n. 11. t. 5. f. 1.—"Leaves denfe; radical ones elliptic, oblong, tapering at the base, doubly and unequally crenate; those of the stem oblong, acute, simply crenate; uppermost roundish-ovate, pointed, slightly decurrent. Clusters denfe. Two of the anthers oblong."—Observed by Mr. Schott in Austria, on a barren soil. Biennial. We cannot but fpject this to be a variety of the last, with a more denfely hairy, more strongly crenate, radical leaves, and broader upper ones. The two species are, at least, very nearly akin.

10. V. nemorosum. Grove Mullein. Schrad. n. 12. t. 1. f. 2.—"Leaves acute, crenate, downy; radical ones oblong, tapering at each end; lower stem-leaves lanceolate, contracted at the base; middle ones oblong-lanceolate; upper oblong, slightly decurrent. All the tufts of flowers a little remote. Two anthers oblong."—Found by Mr. Schott in groves in Austria. Biennial. Akin to V. phluaioides, but distinguished by its straight, wand-like stem, four feet high, with a solitary lax clufker, and the narrow elliptic-lanceolate shape of all its leaves, which are of a yellowish green, the radical ones becoming finally rather nacked on the upper surface.

11. V. montanum. Mountain Mullein. Schrad. n. 13. "Hort. Getting. fae. 2. 18. t. 12."—"Leaves downy; radical ones oblong-elliptical, crenate, flaked; those of the stem oblong, rather acute, slightly crenate; uppermost acute, rather decurrent. Flowers nearly fucculent, in rather crowded tufts. Anthers almost equal."—Native of the Pyrenées, as well as of the Alps of Switzerland and Germany. Biennial. Stem eighteen inches or two feet high, erect, simple, clothed, like the reed of the herbage, with yellowish fluffy pubescent. Leaves somewhat wrinkled, reticulated beneath; the radical ones three to four and a half inches long, two to two and a half broad, obtuse, losing part of their thick downiness by age: lower stem-leaves tapering into a footstalk; the red, acute, fucculent, or, about the top of the stem, slightly decurrent. Clusters from about three to six inches long. Flowers nearly fucculent, in tufts more or less crowded; stem solitary. Bracteas ovato-lanceolate, pointed, scarcely exceeding the flowers, except the uppermost. Calyx in V. phluaioides. Cordula moll a V. Thapsus. Two of the flowers more slightly hairy than the rest, sometimes naked; their anthers perfect, but rather larger and more oval than the three others. If cultivated in shady situations, the stem sometimes reaches the height of six feet, and becomes branched in the flowering part; the leaves also grow much larger, of a dirty green, a little polished on the upper side; the clufkers above a foot long, thicker, and more compact. Schrader.

12. V. collinorum. Hill Mullein. Schrad. n. 14. t. 5. f. 1. —"Leaves crenate, downy; lower ones elliptic-oblong, flaked: those of the middle of the stem oblong-lanceolate, rather acute, tapering at the base; uppermost oblong, acute, slightly decurrent. Tufts of flowers distinct. Anthers equal."—Native of hilllocks, and dry gravelly ground, in some parts of the north of Germany. Biennial. Stem two or three feet high, erect, simple, slightly angular in the upper part; reddish below. Leaves soft, wrinkled, downy on both sides; pale green above; hoary and reticulated beneath; radical ones four or four and a half inches long, and half as broad; the rest gradually smaller upwards, the top ones being about an inch and a half in length. Clusters twelve or eighteen inches long, rarely having a branch at the base. Flowers yellow, sweet-scented, resembling V. nigrum, with purple-bearded filaments, and composing numerous little tufts, often near an inch from each other. Schrader. We should suspect this might be a mule progeny of V. nigrum, impregnated by some of the foregoing species; having found near Norwich what has every appearance of being a familiar offspring of nigrum, from the pollen of V. polyverumelum.

13. V. verziformis. Various-flowered Mullein. Schrad. n. 15.—"Leaves crenate, downy; lowermost elliptic-oblong, flaked; those of the stem oblong, acute, slightly decurrent; uppermost pointed. Clusters panicled. Tufts distinct, of few flowers. Anthers equal."—Found in sandy ground near Prague, but rarely. The herbage is clothed with denfe down, of a dirty yellowish-green hue. Stem two or three feet, or more, in height, branched in the flowering part, rarely simple. Leaves rather thick and rugged; radical ones from three and a half to six inches long, one and a half to two and a half broad, most evidently and acutely crenate at the base; those about the middle of the stem only fucculent. Clusters panicked, a foot long, or more. Flowers generally the size of V. phlomoides, slightly fragrant, in rather distinct tufts. Partial flasks half as long again as the calyx. Bracteas ovato-lanceolate, with long points; the inner ones linear, much smaller. Corolla of a rusty red, but variable, the bafe of its smaller segments bearded with the fame kind of yellow wool that clothes the three smaller filaments. Two larger filaments covered entirely with purple wool, fome of which also is seen about the middle of the three others. Anthers kidney-shaped; those of the two longer filaments rather larger, and finally more oval. Pollen white. Sometimes the corolla is found twice its usual fize, and the partial flower-flasks are occasionally more long and slender than above described. Professor Schrader received this from Mr. Tauch, a Bohemian botaniff, as V. rubiginosum of Waldkein and Kitaibel; a species unknown to us, but which he says is widely different.

14. V. ramigerum. Branched Decurrent Mullein. Schrad. n. 16. t. 4.—"Leaves finely downy; radical ones oblong-lanceolate; those of the stem oblong, acute, doubly cre-
nate, half-decurrent; uppermost pointed. Clusters panicked. Tufts diant, many-flowered. Anthers equal."—Native of the duchy of Mecklenburg-Swerin. Link. The habit of this species resembles V. Lycobitis. Root biennial. Stem from four to fix feet high, erect, thick; rather angular, brown, and much branched in the upper part; the branches spreading, angular, and, like the rest of the item, thinly downy. Upper side of the leaves covered with very thin pubescence; under more hoary, and more thickly clothed; the radical, and lower stem-leaves, often a foot or more in length, four or five inches wide, tapering down into the footstalk. Flowers yellow, from fifteen to twenty in each tuft of the principal cluyfer, on flacks twice the length of the calyx; fewer in the lateral clusters; the lower tufts many of them very distinct from each other. Bracteas ovato-lanceolate. Calyx and corolla larger than in V. Lycobitis. Stamens like those of that species. Schrader.

15. V. mucronatum. Pointed-leaved Mulllein. Lamarck Dict. v. 4. 218. Schrad. n. 17; excluding perhaps Tournefort's synonymy. —"Leaves crenate, clothed with dense hoary down; radical ones oblong-lanceolate; those of the item oblong, acute, half-decurrent; uppermost ovate, long-pointed. Spikes panicked. Flowers in nearly feafe heads." Found in Crete by M. Labillardiere. Root biennial. Whole herbage covered with hoary down. Stem, in the cultivated plant at least, from fix to eight feet high, fliight, thick, branched below. Lower leaves one a half, or two feet long, on short flacks, acute; the rest more pointed, and unequally decurrent. Spikes panicked, various in length, their points somewhat incurved. Flowers yellow, rather large, in diffant, many-flowered, feafe heads, hoary with deciduous woolines. Bracteas lanceolate. Filaments all clothed with whitish wool. Schrader.

16. V. finatum. Scollop-leaved Mulllein. Linn. Sp. Pl. 254. Willd. n. 12. Ait. n. 14. Schrad. n. 18. Sm. Fl. Grac. Sibth. t. 227. unpubl. (V. crispum et finatum; Bauh. Hist. v. 3. 860. V. alius; Camer. Epit. 882. Math. Valgr. v. 2. 492. V. Lacinatum Matthiolii; Dalech. Hist. 1302. Φαυλος μελανος; Dioec. book 4. chap. 104. —Leaves ferrated, powdery; radical ones pinnatifid and wavy; the rest undivided, decurrent. Stem panicked, many-flowered.—Native of dry barren exposed situations, in the south of Europe, and north of Africa; a hardly biennial, long known in our botanical gardens, but seldom long preserved. Dr. Sibthorn observed this to be the most common Mulllein throughout Greece and all the circumjacent islands. The root is brown, and rather woody. Herb of a dark green, besprinkled with loose tufts of powdery, hoary, flary pubescence, but far less woolly, or uniformly hoary, than any of the preceding species. The leaves also differ widely from all the foregoing, in being pinnatilat half way to the midrib, with jagged and plaited lobes; the radical ones a span long, on short flacks; the rest smaller, feafe, decurrent; the upper ones very small, ovato-lanceolate, undivided, more decurrent, reflexed; all of them reticulated with veins, rugose; molt hoary beneath. The stem is erect, one a half or two feet high, zigzag, alternately branched from top to bottom, panicked, often tinged with dark purple. Panicle spreading, with copious, hoary, somewhat winged branches. Flowers generally tufted, ilalked, yellow, with Lorpale hairs. Capule small, roundish. The figure of Matthiolus, copied by D.Lechamp and Tabeneruonanmus, is more like the cultivated variety of the following species, but differs in its branching panicked stem.

Scct. 2. Leaves not decurrent.

17. V. pliicatum. Plaited-leaved Mulllein. Prodr. Fl. Grac. n. 524. Fl. Grac. t. 226, unpubl. (V. finatum; 2; Linn. Sp. Pl. 255. V. pinnatifidum; Ait. n. 15, but not of Vahl nor Willdenow. V. gracum fruticosum, folio finato candidissimo; Tourn. Cor. 8. Voyage, v. 1. 128, with a figure; 200.204.205.206. Dioec. book 4. chap. 103.)—Leaves ilate-sinuate, crisped, somewhat crenate, downy on both sides. Spike simple, interrupted, leafy.—Native of the ille of Hydra, and very plentiful about Athens. Root tapering, possibly perennial. Stem ascend, simple, leafy, clothed, like the floage and calyx, with dense, flary, rigid, yellowish woolines. Leaves obovate-oblong, thick; plaited, acute, or crisped at the margin; their upper surface even, and almost without sign of veins; under reticulated; radical ones ilalked, near a span long; the rest seafe, clasping the stem, and gradually smaller upward; floral ones very small and pointed. Spike solitary, erect, a foot long, leaf, or bracteated. Flowers three or four feafe together in the bohom of each bractea, yellow, almost an inch broad. Filaments yellow, bearded from the middle to the fummit. Anters all nearly alike. Capsule ovate, acute, hard, smooth when ripe. The leaves vary in acuteness; and in the garden plant, raised from Dr. Sibthorp's seeds, become more dilated, flattened, and less crisped, resembling the figure of Matthiolus, cited under our preceding species, but the pubescence still remains totally different.

18. V. auriculatum. Auricled Mulllein. Prodr. Fl. Grac. n. 523. Fl. Grac. t. 225, unpubl. (V. orientale maximum candidissimum, ramis candebsum anmblantibus; Tourn. Cor. 8. —Leaves eliptic-oblong, downy on both sides, auricled at the base. Clusters panicked, zigzag.—Native of the island of Samos. Biennial. The whole herb is clothed with dense snow-white down. Stem two feet high, flat, leafy; branched and becoming smooth in the upper part. Leaves crowded, seafe, two or three inches long, bluntly pointed, accompanied by axillary tufts of smaller ones; their upper surface covered with a dense and even coat of wool, hardly marked by rib or veins; the under reticulated, scarcely less densely clothed with a flary coiwbe-like pubescence: their base contracted, but augmented with a rounded lobe at each side, embracing the item. Flowers yellow, ilalked, tufted and bracteated, as in V. phlomoides, but only half as large. Calyx with smooth points. Beard of the filaments yellowish-white. Anthers orange-coloured, nearly uniform. We think Tournefort's synonymy is here rightly applied, though cited by Lamarck and Schrader for mucronatum, n. 15, which must be a different plant from the present, unless it be inaccurately described.

19. V. pinnatifidum. Pinnatifid Mulllein. Vahl Symb. v. 2. 39. Willd. n. 13, excluding the synonymy of Tournefort, which belongs to our n. 17. —Leaves flat, pinnatifid, cut, powdery; nearly naked on the upper side; radical ones ilalked. Stem panicked, many-flowered.—Behaved by Dr. Sibthorn, on the sandy feashore near Yalta, in Botinia. Root perennial, blackish, divided at the fummit. Stem one to two feet high, erect, very much branched in all directions, leafy, round, dark-purple, sprinkled with downy malefines. Radical leaves three inches long, on base ilalks, flat, deeply pinnatifid, cut, wrinkled and velvety; dark green and almost naked above; pale, and powdery with flary hairs, beneath: the younger ones very densely woolly; those of the item not half as large, feafe, not deciduous; leaf divided: floral ones aggregate, spreading, extending for the most part beyond the flowers, which are feafe, crowded, yellow, hoary externally, with orange-coloured filaments. Capsule nearly globose.

VERBASCUM.

(V. blattariz folleis nigrum, amplioribus floribus luteis, apicibus purpurascensibus; Boerh. Luggd.-Bat. v. 1. 228.)—Leaves oblong, somewhat lyrate, doubly crenate, venous, slightly downy. Spike interrupted. Flowers in nearly sessile tufts. Bracteas all linear.—Said to be a native of the south of Europe. The Linnæan specimen grew in the Upsal garden. This species is very little known, perhaps from Linnæus having cited a plate of Miller's, which is as little like his specimen as almost any Verbascum can be, and belongs to V. phlomoides. Hence V. Boerhaavei is admitted, without sufficient grounds, into the catalogue of our garden plants. We have, at least, never seen any thing answering to it. The leaves are a foot long, and almost four inches broad, membranous, copiously reticulated with veins; pinnaatifid, in a lyrate manner, at the bafe; nearly smooth on the upper surface; the under partly clothed with light, deciduous, hairy wool, resembling moulindes. Spikes (whether solitary or numerous, does not appear from the specimen) a foot long, slightly and loosely woollly, of numerous scattered tufts of large yellow flowers with purple filaments.

21. V. hamorrhoidale. Madeira Mullein. Ait. n. 5. Willd. n. 4.—"Leaves ovate-oblong, downy, slightly and minutely crenate; tapering at the bafe. Clusters elongated. Flowers in sessile tufts, without bracteas."—Native of Madeira, from whence it was brought to Kew by Mr. Mallow, in 1777. This is marked as a biennial greenhouse plant, flowering from June to August.

2. V. Thapfu; Linn. Sp. Pl. 1669. (V. Thapfoides; Willd. n. 2. Ait. n. 3. Huds. 90. Schrad. n. 7. "Hoffmann. et Link Lufft. v. 1. 214." V. anguifolium ramulosum, flore aureo, folio crafiores; Bauh. Hift. v. 3. 862.)—Leaves wedge-shaped, oblong; flumped of down on their upper side. Stem angular, panicked.—Native of pastures, road-sides, and waste ground, in various parts of Europe, flowering in July and August. In England it rarely occurs, except on chalky ground in Kent, where it abounds. The root is biennial, scarcely perennial. Stem a yard high, straight and upright, finely downy; copiously panicked at the top. Leaves elliptic-oblong, tapering at the bafe, crenate, reticulated with veins; white and woolly beneath; dark green and slightly downy, or quite naked, above; those at the root, and lower part of the stem, flaked; the reft fettite, not decurrent, all narrow at the bafe. Branches of the panicul racemose, with many woolly tufts of flaked, rather small, flowers, whole corolla is cream-coloured, tinged with yellow. Filaments yellowish, hairy. Anthers orange-coloured, uniform. The variety B, a very celebrated and much disputed plant, is not preferred in the Linnæan herbarium. It is described as the male offspring of V. Lychnitis, from the pollen of V. Thapfus. We have specimens, artificially produced in this manner, by Mr. Garnth, of Garn, Donegalshire. These agree with the Portuguese plant, font by profeffor Link, as his V. Thapfoides. So that we conceive the real V. Thapfus, or Thapfoides, is before us. Yet there are parts of the Linnæan defcription, Sp. Pl. 1670, that puzzle us; such as the purple board attributed to the filaments of V. Lychnitis and of this variety. Our specimens are intermediate, in every refpect, between Lychnitis and Thapfus. Their corolla is yellow. Beard of the filaments white. Upper leaves somewhat decurrent. As the real species of this genus evidently vary before our eyes, there can be little doubt that their mule progenies are still more uncertainly defined.

B. V. nigro-pulverulentum; Fl. Brit. ibid. Leaves ovate-oblong, obscurly pinnatifid, covered on both sides with powdery deciduous wool. Stem round, panicked, much branched.—Native of banks, and the borders of fields, on a gravelly or chalky soil, in England, Auflria, and Switzerland, flowering in July. This beautiful and flately plant is frequent about Norwich, and molt parts of Norfolk; also near Bury, Suffolk; and, according to Ray, at Wollerton, near Nottingham. No species can be more diftinct from the last, with which it has been confounded, even by Linnæus. The root is biennial. Stem three or four feet high, branched from top to bottom in a conical form, covered with innumerable golden flowers, larger than the last, whole filaments are clothed with white hairs, and their anthers are vermilion. The whole herbage is invested with white mealy down, easily rubbed off. Leaves all fettite, thick and woolly; the rational ones numerous, a foot long; upper ones ovate, pointed, clasping the ftem, not decurrent. Mr. Sieber has lent an Austrian specimen of this species, named V. floccosum; but we know not of its having been published under that denomination.

Our variety B is found near Hadleford, and in other parts of Norfolk. The leaves are like pulverulentum, flowers, and purple woolly filaments, like nigrum; fo that, according to the opinion of Linnæus, the latter was the mother of this apparently mule production. We believe it more to be perennial.

V. pulverulentum displays a remarkable degree of irritability, if the stem be firnaily trucf, twice or thrice, with a fmall flick. In the pace of a few minutes, the flowers close, and begin to drop off, all in their turn falling to the ground in the pace of a quarter of an hour, if the weather be warm and still; if otherwife, this quality is lefs perceptible. We were firft informed of it by the very injoinf Mr. Correa de Serra.

24. V. gallicum. Dauphiny Mullein. Willd. n. 11. (V. Chaixi; Villars Dauph. v. 2. 491. t. 13; fynonyms all very doubtful.)—Leaves ovate-oblong, crenate, downy beneath; radical ones flaked; heart-shaped and pinnatifid at the bafe. Stem angular, panicked at the top.—Native of several parts of Dauphiny, in rocky situations. The habit of this plant, its panicule, and the soft durable pubefcence of the backs of its leaves, as well as the shape of fuch as grow on the stem, molt refembe V. Lychnitis; the yellow flowers, purple hairy filaments, as well as the fize, form, and long fofflakes of the radical leaves, which are doubly crenate, rather accord with V. nigrum. But thefe radical leaves are remarkable for a few deep parallel segments at their bafe. We have a specimen from the author himfelf, or his bad figure would little avai us.

The late Mr. Dunn favoured us with a specimen, above twenty years ago, from the Cambridge garden, of a tall Mullein, agreeing with this in molt refpefts; but the lower leaves are taper at the bafe, and fecrely pinnatifid. This came from Poland, and is doubtful V. polandicum of his Hort. Cantab. ed. 5. 45; but unfortunately a name does not make a species, any more than floccosum of the fame ufeful work, fee our n. 23. This Polifh plant feems a mule between
between nigrum and Lychnitis; or it may be a variety of
gallicum.

Ger. Em. 775. Fl. Dan. t. 1088. (V. tertium; Mattth.
Valgr. v. 2. 489.)—Leaves oblong-heart-shaped, stalked,
waived and crenate, slightly downy. Clutter solitary, spikled,
many-flowered.—Native of banks, and road-sides, in most
parts of Europe. With us it occurs chiefly on a chalkly
or gravelly soil, in shady lanes, or on grassy hillocks,
flowering in July and August. The root is perennial. Stem
corect, simple, angular, leafy, brown or purplish, two or three
feet high, rarely branched. Leaves of a fine deep green,
near hoary, though somewhat downy; all stalked, except
the very small upper ones. Clutter very long, slender, com-
 pact, though here and there interrupted, composed of in-
umerably tufted golden flowers, with bearded yellow fila-
ments, and orange anthers. This is altogether a very ele-
genious species.

We received, many years since, from the late Mr. Davall,
specimens and seeds of a variety of this species, having
white flowers. These dried specimens differ little from our
wild plant, except a slight degree of luxuriance, owing to
culture, nor can it be doubted that they are the white-
flowered variety, mentioned by Cafpar Bauhini, and others.
But the far more luxuriant progeny from their seeds, in
lady Amelia Hume's garden, bore large copper-coloured
flowers, almost like V. cupreum, Curt. Mag. t. 1226, which,
but for its solitary flower-flake, we should believe to be our
plant. Such is the Proteus-like nature of this whimsical
genius!

26. V. ferrugineum. Rusty Mullein. Ait. n. 9, ex-
cluding the reference to Andrews. Willd. n. 7.—"Leaves
somewhat villous, wrinkled; those on the stem nearly
hoary, equally crenate; radical ones oblong-heart-shaped,
double crenate."—Native of the south of Europe; said to
have been cultivated, at Edinburgh, by Mr. Sutherland, in
1693, and marked by Mr. Aiton as a hardy perennial, flowering
from May to August. We have no specimen, but we re-
member to have examined an authentic one in Sir Joseph
Bank's herbarium, which proved totally unlike the Greek
plant of Dr. Sibthorp, figured as ferrugineum by Mr. 
Andrews, which is our V. triflata, hereafter described. Such
errors are excusable in such a tribe. We have a notion that the
specimen betrayed some affinity to V. Boerhaavii, n. 20,
but we dare not affirm it.

Grec. n. 819. (V. ferrugineum; Ait. Repof. t. 162.)
—Leaves elliptical, wavy and partly toothed, nearly
smothe; radical ones stalked. Clutter solitary, simple.
Stem leafy.—Gathered by Dr. Sibthorp on mount Athos.
By his means the plant has been introduced into the gardens
of England, where it proves a hardy perennial, flowering moit
part of the summer, and propagating itself copiously by
seed, without requiring any care. This species differs from
all the foregoing, in its very long simple clutter terminating
the stem, at first drooping, but gradually becoming erect,
and, as it flowers, extending itself to the height of five
feet, being composed of innumerably, feathered, solitary,
spreading, almost capillary partial flaks, each three or four
times as long as its accompanying lanceolate bracteas, and
bearing a solitary inodorous flower, an inch broad, of a
peculiarly dull greenish, or yellowish brown, whose filaments
are densly bearded with purple. Sometimes, from luxuriance,
two of these flaks grow together, but each has always its
own bractea. The whole clutter, bracteae, and obtuse calyx,
are clothed with glandular vilacous hairs. The radical leaves
are numerous, on longish flaks, wrinkled, slightly downy,
a little vificid, green, reticulated with veins; their margin
variously waved, or bluntly toothed; those on the stem
are nearly vificid, ovate or heart-shaped, more or less acute.
We cannot perceive any alteration in this plant after cultivating
it for fifteen years, and yet there is scarcely a permanent
specific character, to distinguish it from the following. Can
Tournefort's Blattaria orientalis, bugula flos, 19c. Voy. v. 2.
83, with a plate, acknowledged to be a variable plant, pos-
fibly belonging to our triflata?

t. 125. Curt. Mag. t. 825. Blattaria flore purpureo;
Ger. Em. 776.—Leaves ovate, crenate, smooth, chiefly
radical and feffile. Clutter solitary, simple. Stem nearly
hoary. —Native of Austria, and the south of Europe. A
hardy perennial, cultivated in England ever since Gerard's
time. It is of more humble growth than the last. Leaves
chiefly radical, and nearly seftile, scarcely at all downy;
their margin simply or doubly crenate. Inflorescence
like the preceding, but the flowers are of a dark violet hue,
and the filaments less hairy. Sometimes the stem becomes leafy,
as in Jacquin's figure, and perhaps, as he represents it,
branched; but we have never seen an image of the latter.

ed. 5. 45. Sims in Curt. Mag. t. 1237. Ait. n. 2.
"Leaves oval, seftile, acutely crenate; smoothish on
the upper side. Stem erect, simple. Flowers spikled."—Na-
tive of mount Caucasus. Introduced into England by Mr.
Loddiges, in 1804. A hardy biennial, flowering from
July to September. This has the aspect of several species
in our first section, the flowers being as large as any of those,
yellow, with orange-coloured, partly hairy, filaments;
and nearly seftile, in a long dense spike. But the leaves
are not decurrent, nor, though downy, at all hoary or woolly.
We have seen no specimen.

Dr. Sims has exhibited in Curt. Mag. t. 1226, by the
name of V. cupreum, a Mullein, whose stalked leaves,
racemose flowers, variegated with tawny-buff and purple,
each on a partial flak of confederable length, all appear to
different from a V. ovalifolium, the bracteas, and calyx like-
wise, being altogether unlike the figure of this species, that,
but for our confidence in its excellent cultivator Mr. Lod-
diges, we could scarcely believe it came up from seeds of the
ovalifolium. Perhaps, as Dr. Sims suggests, the parent
may have been impregnated by V. phanecium, or we would
rather say our triflata. When the plant blooms within-doors,
the corolla is pale yellow, with a purple eye. The inspec-
tion of this plant is enough to daunt the most ardent student
of species of Verbascum, and to cause a general mistrust
of them all.

30. V. virgatum. Large-flowered Primrose-leaved Mul-
t. 550. Ait. n. 12. (Blattaria flore ampio; Ger. Em. 
778. B. magno flore; Bauh. Hist. v. 3. 859. Lob. l.c.
564.)—Leaves ovato-lanceolate, toothed, seftile; heart-
shaped at the base; radical ones downy, and somewhat
lustrous. Stem branched. Flowers axillary, on short flaks,
partly aggregate. — Native of Worcefterhire. Biennial,
flowering in July and August. Stem five or six feet
high. Whole plant green, not hoary, though more or less
covered with short, prominent, often forked, glandular
hairs. The calcular bracteas, which resemble those of a prim-
orose, are always so clothed. Those of the stem are very
numerous, acute, toothed or sharply crenate, broad and
rounded at the base, gradually diminishing upwards. Flowers
from the bofoms of many of the upper leaves, large, yellow,

3 E
of the lowermost four, five, or six together, the rest 
foliarily, as are all those of the weaker branches. Flower-
flakes hairy and viscid, seldom so long as the calyx, whose 
segments are lanceolate, acute, and glandular. Filaments 
bearded with purple. Anthers uniform.

taria flore ite; Ger. Em. 778.)—Leaves oblong-lanceo-
late, acute, smooth, but serrated; lower ones bluntish, 
tapering at the base, or falked. Stem branched, racemose. Flower-
flakes much longer than the bracts.—Native chiefly of the 
southern parts of Europe, rare in England, flowering in 
July. Rose tapering, annual. Stem three or four feet 
high, leafy. Leaves much narrower, and more deeply 
serrated or notched than in the last, the upper ones becoming 
gradually more pointed, and smaller, to the bottom of the 
long fimple eflers, where they are replaced by a small, fo-
litary, lanceolate bracta under each flower-flake, as in V. 
trifol and phanecium. The corolla is smaller than the last, 
bright yellow, more or less ftraked with purple. Filaments 
clothed with purple hairs; sometimes the corolla seems to 
become purple all over.

A fupposed variety, with large white flowers, marked 
partially with purplish-brown at the back, is common in 
gardens; coming up from seed, and remaining unaltered, 
through many successive years. This is Blattaria alba, 
Blub. Pin. 241, but we can di cover no specific difference 
between it and the wild or cultivated yellow-dowered kind.

VER
VER

In the first fort the flowers have an agreeable fcent at a 
little distance; but if smelt too long, or too near, it 
takes leaves pleasant.

The second fort has yellow flowers, which are freaked 
more or less with purple, and is very ornamental, flowering 
from July to November, or even later in mild weather.

It varies with white flowers.

The third fort has a biennial root, and the flowers are of 
a bright yellow colour, and sometimes, but rarely, white.

The fifth fort is remarkable for its straight wand-like an-
gular stem, and cream-coloured flowers, which are produced 
great numbers in a compound clustered terminating ra-
ceme. Sometimes the colour of the flowers is yellow.

The ninth fort has the flowers large in proportion to the 
size of the plant, of a bluee-purple colour, and highly or-
namental, somewhat like the auricula, appearing in May, 
and continue successively in bloom for several months. It 
is a defirable plant to cultivate, especially for decorating 
rock-work.

Method of Culture.—These plants may all be increaded 
by feds, and offsets taken from the roots.

The well-ripened seeds should be fown in the autumn, or 
early spring, in a bed of light mould, or in the borders or 
other parts where they are to remain, covering them lightly 
in. When the plants are up a few inches in height, in 
the bed method, they should be removed into nursery rows till 
the autumn, and they must be removed to where they are to 
remain.

The annual fort is, however, best fown at once where 
the plants are to grow, which is best done in patches.

The offsets of all the perennial forts should be taken off 
in the autumn, or very early in the spring, and be planted 
out where they are to grow. This is better than afterwards 
transplanting them.

They are all hardy plants, that succeed in almost any 
common soil and exposure, in borders, &c.

They afford a good effect in their different foliage, modes 
of flowering, and sweet scent of their flowers, in the large 
borders, clumps, and other parts of pleasure-grounds; the 
larger forts being placed backwards in them.

VERBELIÉT, in Geography, a town of Hungary; 6 miles S.W. of Erlau.

VERBENA, in Botany, among the Romans, was the 
name of some evergreen aromatic shrub, esteemed facred, 
and employed in various solemn ceremonies. Hence it was 
called Hierobotane, and Herba faca. Some derive Verbena 
from verro, to sweep, or cleanse; because the plant might 
be used for cleaning the altars or temples; others from Her-
ben a, corrupted from herba bona, or good herb. But thefe 
rather prove that no good Latin etymology was to be 
found. De This gives a much better, and indeed a direft, 
derivation of the word, from Bullet’s Dictionnaire Celticus, 
where the Celtic name of the plant is said to be Ferfan, 
whence comes, still lefs changed, its English appellation, 
Vervain. The Roman shrub, above alluded to, is sometimes 
thought to have been our Rosmary, which could hardly be the Celtic plant; and we must rely on tradition, 
which has handed down our Common Vervain, the Linnz 
Verbena, with much superflitious celebrity, even to the pre-
rent day, as the Ferfan of our barbarous ancestors. It 
shall, from time to time, makes the fortune of quacks and 
village
VERBENA.

village doctres, whether they aim at notoriety or lucre; and a person named Morley once wrote a pamphlet, recommending the root, to be worn as a charm, in scrophulous disorders, but, as Mr. Curtis remarks, he accompanied it with powerful medicines.—Linn. Gen. 14. Schreb. 20.

Gen. Ch. Cal. Perianth inferior, of one leaf, angular, tubular, linear, with five teeth, one of which is smaller than the rest, permanent. Cor. of one petal, unequal; tube cylin- drical, straight, the length of the calyx, soon dilated and incurved; limb spreading, even half way down into five, more or less unequal, rounded segments. Stam. Filaments four, fetaeous, very short, inserted into the tube of the corolla, and concealing within it, two of them shorter than the rest; anther oblong, incurved. Pist. Germen superior, quadrangular; style fimple, thread-shaped, shorter than the tube; stigma obtuse. Peric. feecally any, except an evanefcent membranous tunic, the calyx containing the seeds, which are either four, or only two, oblong, parallel, crefted, straight at the inner edge, gibbous at the outer. Eff. Ch. Corolla fanned-shaped, rather unequal, curved. Calyx with five teeth. Seeds two or four, with a mem- branous evanefcent tunic.

Obf. We have concurred with many other botanists, in separating from this genus the diandrous species; which moreover have only four teeth to their calyx, and never more than two teeth. (See Stachyclus.) But it does not seem necessary to retain also Zappania, distinguished by its two teeth, and more dense inflorescence, which is as truly epicate in as acknowledged Verbenas.

1. V. mexicana. Mexican Vervain. Linn. Sp. Pl. 28. Willd. n. 6. Ait. n. 1. (V. mexicana, trachelii folio, fructu aparines; Dill. Elth. 407. t. 302.)—Leaves ovate, acute, hairy. Stalks. Calyx of the fruit reflexed, hispid, of two round lobes. Seeds two.—Native of Mexico. Cultivated in Sherard's garden in 1726. A flowery plant, flowering in summer. Stem herbaceous, two or three feet high, square, leafy, rough and furrowed, branched in the upper part. Leaves opposite, on short stalks, strongly ferrated like those of a common nettle, rough with minute rigid bristles. Stalk terminal, falked, crefted, long and slender; lax and interrupted in the lower part. Flowers very numerous, small, pale purple. The calyx when in fruit becomes falked, recurved, and is at all times hoary with bristly hairs. We are not certain that this species has always four perfect flowers. Two of the anthers are most visible m the mouth of the tube.

2. V. flabadosifolia. Oval-spiked Vervain. Linn. Sp. Pl. 27. Willd. n. 7. Ait. n. 2. (V. n. 4. Browne Jam. 116. t. 3. f. 1.)—Leaves ovate, imbricated, ovato-cylindrical. Leaves lanceolate, wavy, toothed, clothed with depressid hairs; hoary beneath. Stem thorny.—Native of the West Indies. Stem spreading five or six feet, woody, but not lathing above two or three years. The leaves are flaked, two or a half inches long, acut, reticulated with veins, flat, not plaited, as the erroneous engraving, after Plumer's drawing, is made to express, but wavy at the margin, with small acute teeth; the upper surface is covered with rigid deprefled bristles; the under with foffor hairs. Stalks hairy, an inch long, about thicke the length of their falks. Of the flammas, feds, or colour of the flowers, we are ignorant.

3. V. globifora. Round-headed Vervain. L'Herit. Stirp. 23. t. 12. Willd. n. 8. (Nepeta maxima, flore albò, fpicis habitiari; Sloane Jam. v. 173. t. 108. f. 1.)—Spikes denfe, imbricated, roundifh-ovate. Leaves ovate, crenate, rhugo, downy. Stem thorny, creft.—Native of South America; perhaps, as L'Heritier thought, of Buenos Ayres. We have from thence a specimen of what like it, but smaller in every part, possibly because it is a wild one. L'Heritier's plant was cultivated at Paris, being a ferd of humble growth, of a strong disagreeable odour. The leaves are shorter and more ovate m the leaf, differing also from that species in being finely and closely crenate, not wavy or toothed. The spikes also are much shorter, nearly globule. Flowers white. Stamens four, all perfect. Seeds two.

4. V. javanica. Java Vervain. Burm. Ind. 12. t. 6. f. 2. Willd. n. 9. (Zappania javanica; Poiret in Lam. Dict. v. 8. 840.)—Spikes denfe, imbricated, cylindrical. Leaves elliptic-lanceolate, crenate, finely downy.—Native of Java. Stem fcapitif, roundifh, clothed, like the reft of the plant, with fine, short, clofe hairs. Leaves an inch and a half long, acute at each end. Flowers in short cylin- drical spikes, on axillary, often opposite, falks, the length of the leaves. Linneas fuppolfed this not to be different from V. flabadosifolia, but they are very unlike in the margin of their falks, as well as in general appearance.

6. V. bonariensis. Clutter-flowered Vervain. Linn. Sp. Pl. 28. Willd. n. 11. Ait. n. 5. Poiret in Lam. n. 13. (V. bonariensis altissima, lavandula canariensis filipic multi- pliea; Dill. Elth. 406. t. 300.)—Spikes aggregate, tufted, level-topped. Leaves lanceolate, felfile, clapping the stem.—Native of Buenos Ayres, from whence it came into She- rard's garden; and is still fecn in fonie curious collections, being a hardy biennial plant, flowering throughout autumn. The stem is often fix feet high, fquare, rough, clothed with long, harif, closely ferrated leaves, and terminating in copious tufts of blue flowers, made up of short spikes, on very long, opposite, panicled falks. Seeds four, linear, fparated, curiously rough on the inner fide.

7. V. rugosif. Rugofe Vervain. Willd. Elth. 633. Pursh n. 8. (V. angustifolia; Michaux Barel-Amèr. v. 2. 14. Ait. n. 7. Poiret in Lam. n. 1.)—Spikes thread-shaped, folitary, terminal or axillary. Leaves lanceo- late, sparingly ferrated, furrowed with veins; tapering at the bale.—In dry fof, by road-fides, particularly on lime- bone, from Pennsylvania to Tennesfie, flowering from June...
to August. Perennial. Not above a foot high. Flowers fine blue.—*Purp.*

8. V. *clavata.* Whorled Vervain. "Fl. Peruv. v. 1. 21. t. 33. f. B." Poiret in Lam. n. 15.—Flowers in umbellate heads. Uppermost anthers club-shaped at the back. Leaves whorled, wedge-shaped, undivided or lobed.—Native of Peru, in sandy situations, flowering in August and September. The *flae* are numerous, erect, much branched, hoary; raked below. Leaves five or six in each whorl; fovee-entire, linear-lanceolate, revolute; others divided or three-cleft, hardly an inch long, moderately downy, a little fringed. *Flowers* terminal, sessile, collected into a head in the form of an umbel, each with one or two linear, oblong, downy, fringed *bracteas.* *Corolla* purplish-red. *Stamens* four. Anthers heart-shaped, furnished by a small club-shaped appendage. *Seeds* four. Poiret.

9. V. *hipida.* Brilly Vervain. "Fl. Peruv. v. 1. 22. t. 34. f. A." Poiret in Lam. n. 16.—Spikes tereate, cylindrical. Leaves obvate or oblong, undivided or somewhat three-cleft, deeply ferrate, half-bracing the *flae.* —Native of Peru, in dry chalky ground, flowering in March and April. The *flae* are numerous, herbaceous, spreading, hispid, a foot high, branched, quadrangular. Leaves opposite, sometimes tereate, hispif, contracted, and in a manner decurrent, at the base, wrinkled, strongly veined, hispid, with deep, tooth-like, often unequal, ferratures; their length two or three inches, breadth one inch. *Flowers* much crowded, in terminal, flaked *spikes,* generally three upon each branch, thick, cylindrical, two or three inches long, the lateral ones much shorter. *Bracteas* foliary to each flower, half-lanceolate, fringed. *Calyx* purplish. Tube of the *corolla* purple; limb pale blue. *Stamens* four. Seeds four. Poiret.

10. V. *baffata.* Halberd-leaved Vervain. Linn. Sp. Pl. 29. Willd. n. 12. Ait. n. 6. Pursh n. 4. (V. altissilama americana, *ipic* multipliea, urtice folis anguifis, floribus cæulescis; Herb. Parad. 242, with a plate.)—Spikes panicled, linear, acute. Leaves lanceolate, pointed, deeply and doubly ferrate; lower ones hastate, or pinnatifid.—By road-fides in wet situations, and on the banks of rivers, from Canada to Carolina, perennial, flowering in July and August. From two to five feet high. *Flowers* purple, sometimes white. *Purp.* The leaves are three inches, or more, in length, rough to the touch, like a fine file. *Spikes* two inches long, becoming longer, and lax, after flowering.

11. V. *triphylla.* Lemon-scented Vervain. L'Herit. Stirp. 21. t. 11. Willd. n. 13. Ait. n. 4. Curt. Mag. t. 307. (Zappania citrodora; Poiret in Lam. Dict. v. 8. 845.)—Spikes panicled. Leaves lanceolate, minutely and diffusely toothed, three in a whorl. Stem shrubby.—Native of Chili, where it was found by the unfortunate Dombyr, (see that article,) and introduced into the gardens of Europe. In Italy, Spain, and the south of France, this valuable shrub is quite naturalized, and its delightfully scented leaves, having the flavour of lemon, are useful in fevers, and other inflammatory disorders, being taken as tea, like balm, hyssop, &c. With us it is a hardy greenhouse plant, flowering in summer. The leaves are of a light bright green, roughish, two inches long, apparently entire to a flight observer, soon drying, and fragrant for a long time afterwards if rubbed. *Flowers* small, pale lilac, in aggregate, panicled, loose, terminal spikes. The specific name of this plant is not well chosen, for so many Peruvian and Chili shrubs having three leaves in a whorl. Ortega, who thought it a new genus, called it *Alcyja citrodora,* and the French retain the latter appellation, as if *citrea* would not far more elegantly express their meaning. But who shall weed the rank wilderens of recent botanic names? In which the venerable fabric reeled of *Lamêna* is almost hidden, like the temples at Paestum, before they were cleared.

12. V. *virgata.* Wand-like Vervena. "Fl. Peruv. v. 1. 20. t. 32. f. B." (Zappania virgata; Poiret in Lam. Dict. v. 8. 845.)—"Spikes assially, ternate, flender. Flowers whorled. Leaves ovate, acute, crenate."—Native of the extensive forrests of Peru, flowering in August and September. A branching *flurb,* ten or twelve feet high, with a very agreeable scent. Leaves flaked, opposite, spreading, three or four inches long, an inch and a half broad; rough on the upper side; veny, wrinkled and downy beneath. *Spikes* generally three from the bosome of each leaf, composing a spreading panicle. *Calyx* downy. *Corolla* white. *Seeds* two. Poiret.

13. V. *lappulacea.* Bur Vervain. Linn. Sp. Pl. 28. Willd. n. 14. Schwart Obf. 16. Jacq. Obs. fafe. i. 37. t. 24. (Sorodonia floribis ipicatis purpurascensibus pentapetaloidis, femine unico majori echantio; Sloane Jam. v. 1. 174. f. 110. f. 1.)—Clusters solitary, lax, simple. *Calyx* of the fruit inflated, roundish. Seeds oblong, tuberculated. Leaves ovate, acute, sharply ferrate.—Native of waife ground and flaty places, in the Wt. Indies. The *flae* are herbaceous, two or three feet high, branched, leafy, square, smooth, hollow. Leaves flaked, two inches long, slightly brilily. *Clutters* from the forks of the stem, long, wax, and flender, of numerous, dilant, little, pale-blue *flowers,* on short partial falks. *Calyx* downy; as the fruit ripens becoming globose, inclosing the four hard *seeds,* which are closely combined, beft externaly with four thick spines. Dr. Spratt, in his *Flora Ind. Oct. 1000,* points out the affinity of this species to his own genus *Ghina,* (fee that article,) founded on *Verbenà cura* sffonis of Linnaeus. The fruit of *Ghina,* however, is a drupa, with a nut of four cells.

15. V. *caroliniana.* Carolina Vervain. Linn. Sp. Pl. 29. Willd. n. 16. Ait. n. 8. Pursh n. 9. (V. carolinensis, melilife folio, afpero; Dill. Eth. 407. t. 301.)—Spikes aggregate, lax and flender. Leaves elliptic-lanceolate, acute at each end, ferrated, nearly feffile; rough above; somewhat downy beneath.—In dry sandy fields, from Carolina to Georgia, perennial, flowering in June and July. *Purp.* Herb eretic, branched, somewhat hairy. Leaves harsh, with minute brily tubercles, on the upper side, an inch and a half or two inches long, unequally, not deepely, ferrated. *Flowers* pale red, very small. *Calyx* brilily, twice the length of the minute, ovate, pointed *bracteas.* Seeds four, oblong.

16. V. *urticifolia.* Nettle-leaved Vervain. Linn. Sp. Pl. 29. Willd. n. 17. Ait. n. 9. Pursh n. 6. (V. folio urtica anguinulare; Rivin. Monop. Irr. t. 57. V. recta canadenis; Morif. feé. 11. t. 25. f. 3. V. peregrina, folis urticae; Dodart Mem. 627. t. 35.)—Spikes aggregate, lax and flender. Leaves ovate, acute, ferrated, flaked, hairy on both fides.—About road-fides and cultivated grounds, from New England to Carolina, perennial, flowering from June to September. *Flowers* very small, white.

VERBENA.
white. Purp. Akin to the half, but taller, and clearly distinguished by its flaked, coarsely ferrated, nettle-like leaves. Bracteas ovate, slightly pointed, shorter than the calyx.

17. V. sertae. Stout Upright Vervain. Venten. Hort. Cell. t. 53. 1805. Exe. Enum. 633. Pursh n. 10. Donn Cant. ed. 5. n. 10. (V. rigens ; Michaux Boral.-Amer. v. 2. t. 14. V. paniculata ; Donn Cant. ed. 5. n. 8.)—Spikes aggregate, corymbose, straight, denuded, oblong. Bracteas taper-pointed, as long as the calyx. Leaves ovate, on short flanks, unequally ferrated, downy and hoary on both sides.—Native of Carolina, and the Illinois country, perennial, flowering in July and August. Purp. A tall, stout, hoary plant, whose stiff round stem is clothed with numerous, coriaceous, veiny leaves, an inch and a half to two inches long, acute, coarsely ferrated; molt downy beneath. Spikes from two to four inches long, in strong plants numerous, crowded at the top of the stem, in a corymbose manner, hoary, imbricated. Bracteas ovate, with taper points, generally exceeding the calyx, whose teeth are also long and slender. Corolla large, of a violet blue.

18. V. diffusa. Spreading Vervain. Poiret in Lam. n. 14. Pursh n. 7.—Spikes very long, lax, panicled, widely spreading. Bracteas acute, about as long as the calyx. Stem erect, much branched. Leaves ovate or oblong-lanceolate, late, ferrated, somewhat downy.—Native of North America; cultivated at Paris, according to Poiret, on whose authority, Mr. Pursh gave this species a place in his Flora. He speaks of it as having a near resemblance to V. urticaefolia, with very small, somewhat purple, flowers. We have seen no specimen.

19. V. paniculata. Compound-panicled Vervain. — Lamarck lllustr. t. 57. Diét. n. 8. Pursh n. 5.—Spikes compound, in a corymbose panicle. Leaves lanceolate, deeply ferrated and jagged; tapering at the base; harsh on both sides, slightly downy.—In the natural meadows of the high mountains of Virginia and Carolina, perennial, flowering in July and August.—From four to six feet high. Flowers very numerous, purple. We have not seen the Paris garden a specimen marked V. paniculata of Jullieu, which answers well to the description by Poiret in Lamarck’s Dictionary, and is doubtless what they all intended. Our specimen indeed is but eighteen inches high, and the leaves are about two inches, not four or five, in length. They taper down into short flanks, and are not much pointed. Both surfaces are rough like a file, as is likewise the square stem, which terminates in a corymbose panicle, of compound or branched spikes. The bracteas are ovate, with a fine point, shorter than the calyx. Corolla rather small.—What we received from the late Mr. Donn of Cambridge, as his V. paniculata, is not this, but our V. sertae, n. 17.

20. V. corombyosa. Corymbose Chili Vervain. "Fl. Peruv. v. 1. t. 22. t. 33. f. A." Poiret in Lam. n. 16.—Spikes aggregate, corymbose. Leaves sessile, triangular-heart-shaped, wrinkled, harsh, deeply ferrated, pointed.—Native of Chili, in wide ground among rubbish, flowering in November and December. The stems are erect, herbaceous, square, a foot high, with opposite branches. Leaves about an inch and a half in length, dirty, brownish, veined, almost triangular. Flowers at the summits of the stem and branches, opposite, three-leaved, the lowermost axillary, all forming a corymb of oblong spikes of violet-coloured flowers. Bracteas lanceolate, taper-pointed. Seeds four. Poiret.

21. V. officinali. Common Vervain. Linn. Sp. Pl. 29. Wildl. n. 20. Fl. Brit. n. 1. Engl. Bot. t. 757; Curt. Lond. Jard. t. 41. Woodv. Suppl. t. 218. Fl. Dan. t. 628. Brown n. 1. (V. communis; Ger. Em. 718; Vervain; Rivin. Monop. lrr. t. 56. Vervainsa; Mattth. Valgr. v. 2. t. 399. Camer. Epit. 757.—Spikes slender, panicled. Bracteas ovate. Leaves deeply cut. Stems mostly solitary, somewehat prickly. Native of warm ground, and road-sides, in most parts of Europe, common in England, flowering in July. We have received it among the first specimens, sent from New South Wales, in 1792, by Mr. John White. Mr. Brown also saw it there, and in the tropics. Vervain is a native of New Holland. The root is perennial, woody, branching, sending up, from each of its summits, a solitary stem, about a foot high, curved at the base, acutely quadrangular, smooth, except a greater or less proportion of minute hooked prickles. Leaves variously jagged, somewhat hairy, tapering at the base into a broad footstalk. Flowers small, pale lilac, in acute spikes, at first denfe, but becoming long and lax as the seeds ripen. Bracteas ovate, half the length of the calyx. Seeds while young enfolded in one common skin, or tunic, almost obliterated as they ripen, when each appears marked at the summit with excavated dots. This is the plant used by Mr. Morley to cure the king’s evil, by hanging its root round the neck. Curtis has very justly expounded his pretensions, and his affected disinterestedness. Ray long ago remarked that the feisable qualities of the Vervain were too flighty to make its many boasted virtues credible. Nevertheless it is still used, and we believe will do no harm; unless the patient be debilitated by this means to neglect what might be more serviceable. Dioscorides, whose V. officinalis, or Holy Herb, this is, first published its powerful use, in incautious, and yet he has been believed for its other qualities.

24. V. pyriflora. Prostrate Vervain. Ait. n. 15.—"Spikes thread-shaped, solitary. Calyx twice as long as the flowers. Leaves deeply ferrated, cut."—Found by Mr. Meares, on the west coast of America, and introduced in 1794 into Kew garden. It is perennial and hardy, flowering in June and July.

VERBENA.
ground in Peru, flowering from March to May. The whole plant is bristly, two feet high, branched. Leaves sessile, half clasping the stem; contracted at the base; divided almost half way down into three large, oblong, serrated lobes, rough and hispid on both sides, two or three inches long, and about as broad. Spikes short, terecinate. Flowers blue. Poiret.

26. V. bracteata. Bracteated Vervain. Michaux Boreal-Amer. v. 2. 13. Willd. Enum. 634. Pursh n. 2. (Zappania bracteata; Poiret in Lam. v. 8. 843.)—Spikes solitary, with lanceolate spreading bracteas, longer than the flowers. Stem decumbent. Leaves laciniate, very hairy. —Native of Illinois and Kentucky, perennial, flowering in July. Flowers light purple. Pursh. A small very hairy plant, said to have some resemblance to V. supina, n. 23, but the long wide-spreading bracteas are peculiar. The stems are from six to nine inches in length. Spikes from the ends, as well as the forks, of the branches, two or three inches long. Seeds only two.

27. V. Aubletia. Roéé-coloured Vervain. Jacqu. Hort. Vind. v. 2. 82. t. 176. Linn. Suppl. 86. Willd. n. 18. Al. n. 11. Pursh n. 1. Curt. Mag. t. 358. (Buchnera canadenis; Linn. Mant. 88. Aublet; Journ. de Rozier, v. 1. 287. t. 2. Erinus lacinatus; Linn. Sp. Pl. 879. Lychnis debena tenuifolius folio; Feuill. Peruv. v. 3. 35. t. 25.)—Spikes capitato, foliatory; cylindrically after flowering. Bracteas awl-shaped, as long as the taper-pointed calyx. Leaves three lobed, cut. Stem erect.—Native of Carolina and Georgia, flowering in June and July. The seeds appear to have been brought to Europe by M. Richard, senior, and were sent by him to Kew garden, in 1774. The plant is biennial in our climate, requiring the shelter of a frame in winter. The herbage is green, roughish to the touch. Stem a foot high, or more, square, leafy, branched from the bottom. Leaves stalked, broadish, variously cut. Flowers larger than most of the genus, of a fine pink or crimfon, numerous, in stalked heads, which afterwards become thick, close, cylindrical spikes. The bracteas are very narrow, permanent, downy as well as the calyx, whose teeth are also very long and slender. Seeds four, oblong; furrowed in the lower, rectangular in the upper, part. This is undoubtedly a genuine and most obvious Verbenae, nor can we account for the error of Linnaeus, who, with the ripe naked seeds on his original specimen, and the long-pointed calyx, referred it to Buchnera. It was called Aubletia, either by its discovery, or by La Tourrette, who lent a specimen and figure to Linnaeus, by which the latter corrected his mistake. Their intention was to honour Aublet, whose name was sometimes written Oblet. With respect to the other Linnean synonym, hitherto neglected by most of those who have noticed this Vervain, it depends entirely on Feuilleé's plate and description, which led Linnaeus to refer this, as well as the following species, to Erinus, without seeing a specimen of either. Lamarck, Poiret, and Willdenow, apply the latter synonyms to their V. erinoides, Willd. Enum. 634, which is V. multifida, Fl. Peruv. v. 1. 21. t. 33. f. C.

28. V. veronicifolia. Speedwell-leaved Vervain. (Eurinus peruvianus; Linn. Sp. Pl. 879. Lychnis veronicéfolia folio, flore comeceo; Feuill. Peruv. v. 3. 36. t. 25.)—Spikes capitato, foliatory, cylindrical after flowering. Bracteas awl-shaped, as long as the taper-pointed calyx. Leaves ovate, serrated, acute at each end. Stem erect.—Found by Feuillée in fields on the north side of the river de la Plata, in Paraguay. This seems to agree with the halt in the flowers and inflorescence, differing only in the simple undivided form of the leaves; but whether that difference be constant and specific, can be determined by future comparison of the two plants. The other synonym of Feuilleé having been misidentified, and, as we premise, distinguished without reason from V. Aubletia, we have here recorded this for the consideration of those who may hereafter meet with materials for solving our doubts.

VERBENA, in Gardening, contains plants of the hardy, herbaceous, and tender exotic kinds, among which the species cultivated are, the Indian vervain (V. indica); the trailing vervain (V. supina); the betony-leaved vervain (V. oru- bica); the Jamaica vervain (V. jacaeincifis); the Mexican vervain (V. mexicana); the globe-flowered vervain (V. globiflora); the clustér-flowered vervain (V. bonarienis); the half-ferted vervain (V. haflata); and the three-leaved vervain (V. triphiylla).

And there are many other species that may be cultivated for variety. The first fort is an annual plant with a purplish flower. In the second fort the flowers are of a light blue colour, and large. The third arises with a shrubby stalk, and the flowers grow in thick terminating spikes about a foot in length; are large, and of a fine blue colour. The fourth fort is three or four feet high in the stem, and much branched, the flowers blooming in succession, beginning at the bottom, but very few together, violet-coloured, with the throat and long slender incurved tube of a white colour. The seventh has four-cornered stalks, which rise to the height of five or six feet, the flowers of which are blue, appearing late in summer. The eighth has many four-cornered furrowed stalks, which are terminated by spikes of blue flowers, in clusters, which appear in August. The ninth is a very sweet-smelling under shrub, and very pleasant, like that of the lemon.

Method of Culture.—These plants are not raised without difficulty or attention. They may be increased by seeds, which should be sown in pots, or on a hot-bed, in the early spring, plunging the pots in the bed. When they are in a state of growth to remove, they should be planted in separate pots, and replunged in a fresh hot-bed, shade being given till they have taken new root, when they must have the management of tender plants of the exotic kind. The annual forts should be kept in the stove, or a glasses cafe, where there is a bark-bed to plunge them in, when too large to be continued under the frames; and the perennial forts may be placed simply in such cafes, air being admitted in a cautious manner.

Of these kinds, such as do not afford good feeds in this climate, may be increased by planting cuttings in the summer months in pots of good mould, placing them in the bark-bed of the stove, where they may be preserved many years. The eighth fort may be raised from seeds by fowing them in the autumn, and by parting the roots and planting them out at the same time. They succeed best on a light loamy soil, and are so hardy as to thrive in the open air. The ninth fort may be readily increased, by planting cuttings in the spring or autumn in pots of good mould. It should have the protection of the greenhouse or a glasses cafe. They afford variety among other potted plants in the greenhouse and stove, and some of the hardy forts occasionally in the open ground.

VERBÉNACA, in Botany, with the earlier botanists among the moderns, and even with Pliny himself, seems to be synonymous with VERBENA, see that article. Linnaeus indeed uses this word as the specific name of a common Englishe species of Salvia, not supposed by any body, that we can find, to have been the so much honoured Verbénaca of the Romans, see Pliny, book 25. chap. 9. He was led to
VERBENICO, in Geography, a town of the island of Veglia, with a small harbour, containing about 1200 inhabitants.

VERBERATION, formed from verbera, I smite, in Phyt生机, a term used to express the cause of found, which arises from a verberation of the air, when brisk, in divers manners, by the several parts of the sonorous body first put into a vibratory motion.

VERBÉRIA, in Geography, a town of France, in the department of the Oise; near it is a medicinal spring; 9 miles S. of Compaigne.

VERBÉSINA, in Botany, according to Ambrosius, who is followed by Linnaeus, Phil. Bot. 175, originated in Verbesina; which latter arose from the leaves being divided like a pair of forceps. Professor Martyn, however, derives Verbesina from λεύκα, food, or fodder; the chief objection to which is, that the plants of this genus do not appear to be serviceable, or to have been recommended, for any such purpose. De Theis confides the above name as synonymous with Verbenia, because, as he says, the undulated obtuse leaves of Verbesina alata resemble that plant; but this explanation is unauthorized.—Linn. Gen. 437. Schreb. 570. Willd. Sp. Pl. v. 3. 2221. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 120. Pursh 564. Juss. 188. Lamarck Illutr. t. 684. Gartn. t. 17 I. (Sylnebela: ibid. t. 17 I.)—Chiós and order, Styngeácha Polynaginá-super-flua. Nat. Ord. Compeata opposiféli. Linn. Cymbrifòræ, Juss.

Gen. Ch. Common Calyx concave, of several oblong, channelled-concave, erect, more or less equal leaves, in a double row. Cor. compound, radiated; that of the numerous perfect florets in the disk funnel-shaped, five-toothed, erect; of the few (about five) female florets of the radius ligulata, either broad and three-cleft, or very narrow and undivided. Stem, in the perfect florets, Filament five, capillary, very short; anthers united into a cylindrical tube. Pfl. in the same florets, German rather oblong; style thread-shaped, the length of the flaments: fligmas two, reflexed; in the female ones, the same. Peric. none, except the unchanged calyx. Seeds in all the florets alike, solitary, thickish, angular, crowned with a chaffy crown of two, or more, acute teeth. Recept. covered with deciduous chaffy scales.

Obf. We have shown, under the article PIKEATHINA, that the genus established by Gartn., with that name, is a real Verbesina, though a Siegebeckia of Linnaeus. The brilliantly-pointed crown of the seed in the genus before us being wanting in V. Taverna, alta, and profeta of Linnaeus, the two latter are removed to Eclipta, and the first to Taverna; see those articles. The number of radiant florets is uncertain in many species.

Seef. 1. Leaves alternate. 1. V. alata. Wing-falked Verbesina. Linn. Sp. Pl. 1270. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 1716. (Cannabina indica, folis integris, alato caule; Magn. Hort. 40. t. 8. Chrysothamnem americanum, caule alato flore aphylo globo antalian, foliis barcarolais; Commel. Hort. v. 1. t. 3. C. corallaviacum, alato caule, floribus aurantius; Herm. Parad. 125, with a plate.)—Leaves alternate, decurrent, undulated, bluntnish. Brilles of the seed two, very unequal.—Native of South America and the West Indies. Cultivated ever since the beginning of the last century in our floues, where it flowers most part of the summer, and being not uncommon, has been figured in more publications than we have thought necessary to quote, but which are cited by those mentioned above. The plant is perennial, hoary when young, erect, branched, three or four feet high, readily known by its winged stem. Leaves three or four inches long, veiny, wavy and toothed. Flowers of a very rich orange-colour, almost globular, three quarters of an inch broad, on long naked, alternate, often purplish, flalks, at the ends of the branches. Florets of the radius, in our gardens at least, numerous. Seeds bordered with a membrane; their terminal awl-shaped, rigid, one much longer than the other, incurved and hooked. Linnaeus has hinted that this species differs so much in habit and structure from the rest, as almost to constitute a distinct genus. Gertner makes it the type of Verbesina, and yet affirms that this genus is only Spilanthus with a radius. Indeed these two genera do run very much into each other, and the radius occasionally appears or vanishes in several species of each, nor are the bristles of the seed perhaps strictly constant even in the same species. We fearfully think the difficulty would be much lessened by removing V. alata to Spilanthus, fee that article; though such a measure might be sanctioned by the habit of the plant. The remaining species, very various in habit, have not been sufficiently examined or compared to allow of a clear decision respecting them, and we must take them in general as we find them.

2. V. chinesis. Chinese Verbesina. Linn. Sp. Pl. 1270. Willd. n. 2—Leaves alternate, falked, ovato-lanceolate, obtuse. Seed-down with four bristle points.—Brought by Olbeek from China. Stem shrubby, with round, leafy, downy branches. Leaves an inch and a half long, bluntly serrated, finely downy. Flowers: the size of the preceding, yellow, with numerous short rays, growing about the ends of the branches, on long, thinly leafy, nearly simple, flalks. Seeds slender, quadrangular, each crowned with a jagged membrane, and four small, erect, straight bristles.

4. V. virginia. Wool-falked Verbesina. Cav. l. v. 3. 38. t. 275. Willd. n. 4—Leaves alternate, lanceo- late, serrated, tapering at each end. Flowers corymbose. —Native of Mexico. Perennial, flowering in the garden at Madrid in December. Stem four inch high, erect, wame-like, leafy. Leaves a span long, tapering down into the feet-like. Flowers yellow, an inch broad, with about two elliptical radiant florets. Seeds black, elliptical, bordered with a white hish, and crowned with two small, erect, often deciduous bristles.

5. V. mutica. Parsley-leaved Verbesina. Linn. Sp. Pl. 1273. Willd. n. 5. Ait. n. 2. Swartz Obs. 314. t. 8. f. 1. (Bident apicalita; Linn. Am. Acad. v. 3. 425. Chrysothamnem paluster minimum regionis, apicis foliis; Shone Jam. v. 1. 263. t. 125. f. 3. C. humile, ramunculai foliis; Plum. Ic. 75. t. 65. f. 2.)—Leaves alternate, deeply three-cleft, toothed; radical ones obovate, serrated. Stem prosthente. Seeds without awn.—Found in rather moist meadows, and by waysides, in the West Indies. Swartz. Miller cultivated it in 1768, from seeds sent by Houttoues, from whom Gronovius received specimens in 1732.
species, having no brilly crown to the feed, belongs rather, as Dr. Swartz observes, to Anthénes; but the habit is somewhat adverte. The flėms, a span long, spread every way on the ground, and are leaffy, more or less branched. Leaves much divided and toothed; glaucous beneath. Flowers small, yellow, with numerous radiant florets. Red bordered.

6. V. Bofwallea. Fennel-leaved Verbesina. Linn. Suppl. 379. Wild. n. 6.—Leaves alternate, three-leaf, with many capillary segments. Stems profuse. Seeds hairy, with two bristles. Female flore foliary.—Native of the East Indies. Used by the natives in fomentations. An annual, herbaceous, decumbent plant, having the taft and smell of fennel; the divisions of the leaves also resembing that herb, only shorter and fewer. Flowers mostly foliary, axillary or terminal, falked. Calys-scales few, broad, elliptical, with a membranous edge. Florets five or six only; of which one is ligulate and female; the reft four-leaf. Seeds comprefled, black, clothed with fhaggy golden hairs, and crowned with two black bristles. Linneus, or rather Köning, who fent him this plant, appears to have had an intention of making it a new genus, by the name of Bofwallea, which might have been done without violence of nature. We are not informed of the origin of the name.

7. V. gigantes. Great Pale Verbesina. Jacq. Coll. v. 1. 53. Lc. Rar. t. 175. Wild. n. 7. Ait. n. 3. Swartz Ind. Occ. 1368. (Bidens frutecens, fphonolii folio et facie; Plum. Lc. 41. t. 31.)—Leaves alternate, pinnatifid, finnated, toothed. Stem thrifty.—Native of mountainous thickets, in Jamaica and other parts of the West Indies, flowering in December and January. Though often seen in our more curious flow collections, it very rarily flowers. The flėm is ten or twelve feet high. Leave deep pinnatifid; downy beneath; the lower ones twelve to eighteen inches long. Flowers small, white, or fleff-coloured, numerous, in large, corymbofe, terminal panicles. Seeds, according to Jacquin, crowned with a foliary brifite.

8. V. Coreopûs. Alternate-leaved Winged Verbesina. Michaux Boreal.—Amer. v. 2. 134. Pursh n. 3. (Coreo- fûsis alternifolia; Linn. Sp. Pl. 1283. Wildl. Sp. Pl. v. 3. 2257. Jacq. Hort. Vind. v. 2. 50. t. 110. Chrysanthe- mun virginianum, caufe alato, ramofius, flore minore; Pluk. Phyt. t. 159. f. 3. C. caule alato, virginianum, &c.; Morif. feet. 6. t. 7. f. 75. 76.)—Leaves alternate, lanceolate, ferrated, falked. Stem winged. Panicle corymbofe, leaffy.—On the mountains of Virginia and Carolina; perennial, flowering from July to September. From three to five feet high, the flėm furnifhed with feveral narrow, green, entire, leafy wings. Leaves four or five inches long, roughfed on the upper fide; the lower ones opposite, or three or four in a whorl; but the greater part are alternate. Flowers ferial, in a downy-falked branched panicle. Calys widely spreading, almost flat, fo that the disk becomes nearly globose, fubtended by four or five orange-coloured, spreading, ligulate florets, near an inch long. Seed crowned with two short briftles. This species is naturally very nearly allied to V. Siegfèckia, hereafter defcribed, fee n. 11, nor can they be genericafy feparated.

Michaux and Pursh mention a white-flowered variety, always deftite of rays, found by the latter on the coaft of Carolina, which is Athanaia paniculata, Walt. Carol. 201. This Mr. Pursh ftrongly fupiceps to be a very diftinft species.

9. V. bilanbboides. Sun-flower Verbesina. Michaux Boreal.—Amer. v. 2. 135. Pursh n. 4.—"Leaves alternate, broadly lanceolate, acute, slightly toothed; rough above; downy and hoary beneath. Stalks fingle-flowered, aggre-

10. V. pinnatifida. Pinnatifid Yellow Verbesina. Cavan. Lc. v. 1. 67. t. 100. Wild. n. 8. Jacob. Hort. Schoenbr. v. 3. 30. t. 305.—Leaves oppofite, pinnatifid, ferrated. Stem winged.—Native of Mexico, flowering in the European frows in December and January, but not yet known in the Englith collections. The flėms are feveral, rather thrifty, with four, fightly fwarf, membraneous wings. Leaves about a foot long, tapering at the bafe. Inflorescence like V. gigantes, but the flowers are more numerous, yellow, with feveral conspicuous rays. Seed crowned with two briftles.

11. V. Siegèfèckia. Half-rayed Verbesina. Michaux Boreal.—Amer. v. 2. 134. Wildl. n. 9. Ait. n. 4. Pursh n. 2. (Siegèfèckia occidentalis; Linn. Sp. Pl. 1269. Phäthuhus americana; Garenw. v. 2. 425. t. 169. Pursh 510. Chrysanthemum americanum, caufe alato, amphi- fbus folis binatis, floribus e palate fufceptoibus parvis; Pluk. Mant. 46. t. 334.)—Leaves oppofite, ovato-lan- cate, ferrated, falked; tapering at each end. Stem winged.—In fhady woods, from Virginia to Carolina; perennial, flowering from July to September. A tall herbaceous plant, with four, or more, narrow, uninterrupted wings, running along the flėm and branches. Leave six inches long, undifeged, bright green; roughfed above; downy beneath; the upper ones fometimes three in a whorl. Panicle terminal, forked, downy, leaffy. Radiant florets from one to three, near an inch long, ligulate, bright yellow. We have already (fee Phäthuhus) given reasons for the above fyno- myms. Purh rightly fupiceps thefe two plants to be the fame, but retained Phäthuhus out of deference to Michaux, who neverthelefs has omitted it in his Flora.

12. V. ferrata. Serrated Downy Verbesina. Cavan. Lc. v. 3. 7. t. 214. Wildl. n. 10. Ait. n. 5.—Leaves oppofite, flalked, ovato-lanceolate, with tooth-like farrures; downy beneath. Flowers corymbofe.—Native of Mexico. We have a garden fpecimen from the original author. Mr. Lambert received feeds from him in 1823. The root is perennial. Stems three feet high, erect, round, clothed with white cottony down, espefially when young. Footflaks short, combined by a dilated downy bafe. Leaves three inches long, ftrongly and unequally ferrated; green, but rather fiky, above; more hoary, and denfly downy, beneath, clofely reticulated with veins. Flowers yellow, numerous, in a downy corymbofe panicle. Outer calyx-leaves obovate, recurved. Ray four or five, broad, toothed. Seeds bordered, crowned with two short briftles.

13. V. euanthophila. Five-ribbed Verbesina. Wildl. n. 11.—Leaves oppofite, ovate, ferrated, with five combined ribs; their under fide downy. Flower-flaks race- mofe, panicled, axillary.—Native of the neighbourfhood of Acapulco, in Mexico. The flėm is round, erect. Leaves on short flaks, oblong-ovate, bluntly ferrated, veiny, clothed on both fides with fhort scattered hairs; rough beneath. Flower-flaks long, from the bofsoms of all the upper leaves. Akin to the following. Willdewow.

14. V. bi flora. Twin-flowered Verbesina. Linn. Sp. Pl. 1272. Wildl. n. 12. ("Valliamanga-nari; Rhede Hort. Malab. v. 10. 79. t. 40." Wildl.)—Leaves oppofite, flalked, ovate, ferrated, with three combined ribs; their under fide paler, scarcely downy. Flowers folitary or in pairs, on axillary and terminal flaks.—Native of the East Indies. The flėm appears to be herbaceous, or fightly thrufby,
shrubby, with forked and subdivided, striated, nearly smooth, leafy branches. Leaves two inches or more in length, pointed, their three ribs united a little above the base; their upper side rough with minute depressed bristles; under smooth, or beprinkled with softer hairs. Flower-flasks long, either from the forks of the branches, or about their extremities, bearing one or two yellow flowers, an inch broad, almost always accompanied by a lanceolate leaf opposite to each partial flask. Outer calyx-flakes ovate, bright. Radiant flowers several, elliptical, toothed at the end. Seeds abrupt, triangular, deftuate of a crown, or terminal bristles. The scales of the receptacle are obovate, concave, furrowed, abrupt, rough at the extremity, resembling the inner leaves of the calyx. Linneus points out the affinity of this species to his V. Lavenia; but this regards their habit only, for Lavenia, now a separate genus, (fee that article,) has a naked receptacle, and three bristles to the seed.

15. V. latifolia. Oil-leaf Verbeisia. Sims in Curt. Mag. t. 1017. Ait. n. 6.—Leaves opposite, oblong, clasping the stem, disjunctly forked. Calyx simple, of five leaves.—Native of the East Indies; cultivated in the Myfory country, and several other parts of India, for the sake of the expressed oil from its seeds, which serves as a substitute for that of Sesamum. Dr. Roxburgh sent some of these seeds in 1805, to Mr. William Salisbury, the affidavit possessor of the botanic garden at Brompton. The plant is annual, either to be kept in the house, or raised on a hot-bed, and then planted out, flowering in autumn. Leaves four inches or more in length, green, not hoary. Flowers yellow, two inches broad, with about eight large broad petals, jagged or toothed at the end. These flowers stand on long simple stalks, from the forks of the stem, and bofoms of the upper leaves. The simple calyx, of five broad leaves, agrees with that of the next species; so that, as Dr. Sims observes, if one be reckoned a Verbeisia the other must. We are not inclined to disturb them, because the whole genus, though in many respects very natural, still labours under some strange exceptions and anomalies, which sought all to be well confederated by those who attempt a reform.

16. V. calendulacea. Marigold Verbeisia. Linn. Sp. Pl. 272. Willd. n. 13. Ait. n. 7. (Caltha flore foliario, ex alia foliorum lonicersimo pedunculo prodeuenta; Burm. Zeyl. 52. t. 22. f. 1.) "Pee Cajoni; Rheo Hort. Malab. v. 10. 83. t. 42.)"—Leaves opposite, oblong-lanceolate, very remotely toothed, sessile; tapering at the base. Calyx simple, of five leaves.—Native of Ceylon, and other parts of the East Indies; cultivated by Miller. An annual rove-plant, flowering from July to September. The stem is branched, clothed, as well as the leaves, with rigid depressed bristles. The upper surface of the latter is, besides, usually rough with callosous tubercles: their length and shape are variable, and their marginal serrations are few and remote. Flowers yellow, not half the size of the ball, on long, simple, mostly axillary, stalks. Radiant flowers from five to eight, or ten, elliptical, toothed. Seeds very numerous, composing a globular head, wedge-shaped, abrupt, each crowned with two short bristles.

at Chelms, and in Sherard's garden, being a tender annual, raised and kept in the house, for the sake of curiosity, but having nothing to recommend it to popular notice. The stem is erect, a foot high, branched from the base. Leaves two or three inches long, broadly ovate, tapering suddenly into a winged footstalk. Flowers solitary, or in pairs, small, yellow, with several emergent rays. Calyx certainly of two very different rows of scales, though the outermost confins of but two falcate ones. Seed crowned with two rigid awns.

18. V. dichotoma. Forked Verbeisia. Willd. n. 15. Ait. n. 9. Murray in Camb. Quart. for 1779. 15. t. 4.—"Leaves opposite, ovate, pointed, serrate, hairy, with three combined ribs. Stalks axillary, fiddle-flowered. Stem forked."—Native of the East Indies. Annual. Whole herb beset with copious, short, white hairs. We have seen no specimen.

19. V. fruticeps. Shrubby Weil Indian Verbeisia. Linn. Sp. Pl. 1271. Willd. n. 16. Ait. n. 10. (Bidens fruticetmis, folio folio, flore luteum; Plum. ]c. 42. t. 52.)—Leaves opposite, fiddle-flowered, ovate, serrate, with three combined ribs. Stalks fiddle-flowered, axillary. Stem shrubby.—Native of the West Indies. We have a specimen from Dr. Swartz, though this species is not mentioned either in his Prodromus or Flora. The stem is woody, repeatedly branched and forked. The leaves appear to vary in hairiness, as well as size, but are always rough with minute tubercles. Flowers yellow, with numerous broad rays. Seed compressed, crowned with two bristles.

VERBEISIA, in Gardening, affords plants of the herbaceous and woody flowering exotic kinds, among which the species cultivated are, the wing-flaked verbeisia (V. alata); the Chinese verbeisia (V. chinenis); the fiddle-flowered verbeisia (V. nodiflora); the shrubby verbeisia (V. fruticeps); and the tree verbeisia (V. gigantea). The frill is an herbaceous perennial plant, with the flowers in fiddle heads, of a deep orange-colour, appearing most part of the summer.

The second is a shrubby plant with yellow flowers.

The fourth riles with a shrubby flalc feven or eight feet high, and has yellow flowers.

Method of Culture.—These plants may be increased by sowing the seeds upon a moderate hot-bed, or in pots plunged into it, in the early spring months: and when the plants are of sufficient growth, they should be removed into separate pots, or into a new hot-bed, giving shade till they become new-rooted; afterwards managing them as tender annual plants, being careful not to draw them up weak: about the middle of summer they may be taken up with balls to their roots, and be planted in a warm sheltered border, being protected and watered till re-rooted, little care being afterwards necessary; these produce seeds often in the autumn; but in the house they may frequently be preferred over the winter.

They produce variety in flower and greenhouse collections, and sometimes in the borders during the summer season, especially the frill for its orange flowers.

VERDIAGE, in Grammar and Rhetorics. See VERBOSITY.

VERMICI, in Ancient Geography, a people of Africa, in Mauritania Tingitania.

VERBIEST, FREDERICK, in Biography, a celebrated millennial, was born in Flanders, and attained distinction as a mathematician in China about the beginning of the 17th century. He was appointed by the emperor Cam-Hi president of the tribunal of mathematics, and entrenched with the care of the Calendar. He also obtained permission to
preach the Christian religion in China, and made many efforts for inducing the emperor to embrace the Christian faith; but though Verbiest succeeded in prevailing with him to acknowledge his belief in one God, he failed in his attempts to convert him to Christianity. Such, however, was the respect which the emperor entertained for this missionary, that on occasion of his death, in 1688, he composed an eulogy upon him, and ordered him to be interred with Christian honours. The principal work of Verbiest is entitled, "Altronomia Europaea, sub Imperatore Tartaro-Sinico Cam-Hi, ex umbra in lacem revocata a P. Ferdinando Verbiest, Flandro-Belga, e S. J. Academice Altronomico in Regia Pequinensi Praefecto;" Dilinge, 1687, 4to. He also caused to be constructed, at the request of the emperor, a variety of altronomical instruments, and wrote sixteen volumes, in the Chinese language, on their construction and use. Verbiest contrived likewise to convoy over a long bridge, by means of pulleys, several immense blocks of stone for building a mausoleum for the emperor, which, it is said, 500 horses could not have drawn, and extended an aqueduct several furlongs over a wide plain. He moreover called upwards of 130 pieces of brass cannon for the use of the Chinese government, and calculated altronomical tables with eclipses of the sun and moon for 2000 years. Montsela Hilt, des Mathem. Gen. Biog.

VERBINUM, in Ancient Geography, a town of Belgic Gaul, belonging to the Veromandui, upon the route from Bagacum Nervorum to Durocortorum, between Buronum and Catuacula. Anton. Itin.

VERBO, in Geography, a town of Hungary; 16 miles N.W. of Leopoldstadt.

VERBOSANIA, a town of European Turkey, in Bofnia; 15 miles W.N.W. of Bosnafair.

VERBOSITY, in Rhetoric, an offence against energetic and vivid brevity or conciseness in writing. This differs from pleonasm; as in the latter, words are used which make no addition to the sense, whereas in the verbosian manner, not only single words, but whole clauses, may have a meaning; but it would be better to omit them, because their meaning is unimportant; and therefore, instead of enlivening the expression, they make it languish. Another difference is, that in a proper pleonasm, a complete correction is always made by expunging; but this will not always answer the purpose of the verbosian style, as it is often necessary to alter as well as to raise. Moreover, verbosity does not mean the same thing which the French express by the term "verbiage," which is commonly understood to denote a parade of fine words, plausibly strung together, so as either to conceal a total want of meaning, or to disguise something weak and inconclusive in the reasoning. The former, or verbosity, is merely an offence against vivacity; but the latter is more properly a transgression of the laws of periphrasis. One infallence of a faulty exuberance of words is the immoderate use of circumlocution. In some circumstances circumlocution is a beauty, in others it is a blinheit. It is often used for the face of variety; sometimes for the sake of decency: at other times, propriety requires the use of circumlocution, as when Milton says of Satan, who had been thrown down headlong into hell,

"Nine times the space that measures day and night
To mortal man, he with his horrid crew
Lay vanquish'd rolling in the fiery gulf."

In this case, "nine days and nights" would not have been proper, when speaking of a period before the creation of the sun, and consequently before time was portioned out to any being in that manner. Sometimes even the vivacity of the explication may be augmented by a circumlocution, as when it is made to supply the place of a separate sentence. An instance to this purpose occurs in the words of Abraham, (Gen. xviii. 25.) "Shall not the judge of all the earth do right?" This circumlocution for God serves as an argument in support of the sentiment, and conduces more to conciseness. Such also is the verbosism employed by Cicero, who, instead of saying simply, Milo's domestics killed Cladius, says, "they did that which every master would have his servants to do in such an exigence."

Another source of language in the style is the infusion of such claues, as to a superficial view appear to suggest something which heightens, but on reflection are found to presuppose something which abates the vigour of the sentiment. Such is the following sentence from Swift: "Neither is any condition of life more honourable in the sight of God than another, otherwise he would be a respecter of persons, which he affures us he is not." The last clause enervates the thought, as it too plainly implies, that without this assurance from God himself, we should naturally conclude him to be of a character very different from that here given him by the speaker. Akin to this is the juvenile method of loading every proposition with aspersionations. Such a practice in conversation tends to suggest a suspicion of the speaker's veracity, rather than to engage the belief of the hearer; and it has a somewhat similar effect in writing. Thus in our translation of Gen. ii. 17, God is represented as saying to Adam, concerning the fruit of the tree of knowledge, "In the day thou eatest thereof, thou shalt surely die." The adverb surely, instead of enforcing, enfeebles the denunciation. Another example, somewhat similar, is the manner in which our interpreters have attempted, in the New Testament, to strengthen the negative, wherever the double negative (οὐχ οὔ) occurs in the Greek, even in the most authoritative threatenings, by rendering it sometimes in no cafe, sometimes in no wife; neither of which phrases expresses more than the single adverb not; and as they partake of the nature of circumlocution, they in effect debilitate the explication. Another caue of a languid verbosity is the loading of the style with epithets. Epithets used sparingly, and with judgment, serve to enlivcn the explication; but a profusion of them has an opposite tendency. Besides, they lengthen the sentence, without adding proportionable strength. We may also add, that the crowding of epithets into a discourse betrays a violent effort to say something extraordinary; and nothing is a clearer evidence of weakness than such an effort, without a correspondent effect.

There is, however, one kind of composition, the paraphrase, of the style of which verbosity is the proper character; because it is the professed design of the paraphrast to say in many words what his text expresses in few. Another species of verbosity is a proximity in narration, arising from the mention of unnecessary circumstances. Campbell's Philosophy of Rhetoric, vol. ii.

VERBOVETZ, in Geography, a town of Croatia, at the conflux of the Clerets and Giocova; 7 miles N.E. of Iviatiz.

VERBRO, A A, a river of Denmark, in North Jutland, which runs into the sea, 6 miles W.N.W. of Hioring.

VERBROECK, a town of Flanders; 8 miles E.S.E. of Hulst.

VERCEL, a town of France, in the department of the Doubs; 11 miles N.E. of Ornans.

VERCELLA, in Ancient Geography, a town of Italy, in Gallia Tranispadana, and the capital of the people called Sefitae. It had within its territory a temple and a wood consecrated
consecrated to Apollo. Here the Cimbri were defeated by
the Romans, under Marius and Catullus. After the decline
of the Roman empire, it became a republic, and from that
state it fell under the dukes of Milan; and, lastly, it was
given as a marriage portion to Amadeus III., duke of
Savoy. See VERCELLI.

VERCELLI, or Vercell, in Geography, a town of
Piedmont, and, under the French dynasty, the capital of
the department of Savoia; which see. It is situated at the
junction of the Cerva with the Sesia, and was anciently
called Vercelle. It is the see of a bishop, suffragan of the
archbishop of Milan. There are two churches which are
called cathedral, and twelve others, two abbeys, nineteen
convents of both sexes, three provostships, two priories,
three poor-houses, and five hospitals; the inhabitants are
about 26,000. In 1800, the French took Vercelli from the
Austrians, with considerable losses; 30 miles S.W. of
Milan. N. lat. 45° 22'. E. long. 8° 26'.

VERCHATURSKY, Gorny, mountains which divide
European and Asiatic Russia, extending almost north and
south to a great length, and about 40 miles in breadth.
They are covered with wood, fir, larch, birch, &c.

VERCHEN, a town of Anterior Pomerania; 6 miles
S.W. of Demmin.

VERCHES, Les, a town of France, in the department
of the Mayne and Loire; 10 miles S.W. of Saumur.

VERCHIERE, a town of Canada, on the right bank
of the St. Lawrence. N. lat. 45° 47'. W. long. 73° 9'.

VERCHODVERSKOI, a town of Russia, in the gov-
ernment of Viatka; 40 miles N. of Viatka.

VERCHOJANSKOI, an oligog of Russia, in the gov-
ernment of Irkutsk, on the Yana. N. lat. 65° 40'. E.
long. 138° 14'.

VERCHOKIZLOSKAI, a fort of Russia, in the gov-
ernment of Irkutsk, on the Lena; 120 miles N. of Irkutsk.
N. lat. 54°. E. long. 105° 34'.

VERCHOTOMSKAI, a town of Russia, in the gov-
ernment of Kolivan; 32 miles N.N.W. of Mungatokoi.

VERCHOTURA, a town of Russia, in the province
of Ekaterinburg, near the river Tura. This was the first
town which the Russians built in Siberia. It has four
churches and two convents, besides chapels; and is the see
of a bishop. Verchotura is situated on a rising ground,
and fortified with pallisadoes and a ditch, and defended by
a garrison under a commandant. The adjacent country is
inhabited by a people called Vogulits, who live on fruits
in huts among the woods, employing themselves in hunting
and shooting, without agriculture. In the beginning of
the 18th century, they were many of them converted to
Christianity, and now mix probably with the rest of the
people; 120 miles N. of Ekaterinburg. N. lat. 58° 45'.
E. long. 60° 14'.

VERCHOVAGSKOI, a town of Russia, in the gov-
ernment of Vologda, on the Vaga; 48 miles S. of Vielik.

VERCHOUALSK, a town of Russia, in the govern-
ment of Ural, on the Vara; 120 miles S.E. of Ural.
N. lat. 53° 56'. E. long. 59° 14'.

VERD, or Verde, Cape, a cape on the west coast of
Africa. N. lat. 14° 48'. W. long. 17° 31'.

VERD, or Verde Islands, Cape, islands of Africa, in the
Atlantic, deriving their name from the cape opposite to
which they are situated, and discovered by the Portuguese in
1446. They are so called, as some say, from a green plant,
called Sargallo, resembling water-cresses, and bearing fruit
like a gooseberry, which is found floating near them, and
in such abundance as to impede the progres of vessels in
their course. They are usually reckoned ten in number,
but the remaining rocks, they amount to fourteen. The
two largest are St. Jorge and Santa in the south-east and St.
Anthony in the north-west. Four of these islands are situated
towards the east, viz. Santiago, Mayo, Bonavista, and
Salt isle; four towards the north-west, viz. St. Nicholas,
St. Lucia, St. Vincent, and St. Anthony; and two are
somewhat detached towards the south, viz. Brava and
Fuego. (See each island respectively.) These islands are
generally mountainous; some of them are barren and un-
inhabited; others are productive of rice, bananas, oranges,
cotton, and sugar; and it is said the goats produce thrice a
year, and the vines twice; they abound with poultry and
rabbits, and turtles are plentiful on the shores. The air is
hot and infaluruous, rain being very rare; but a north-east
breeze commonly rises before four in the afternoon. The
manufacture of leather and felt constitutes the chief riches.
Many of them have been furnished by their proprietors with
cows, goats, hogs, asses, mules, &c. These islands are situate
about 350 miles W. of Cape Verde, and between 15° and
18° of N. lat.

VERDACHELON, a town of Hindooftan, in the
Carnatic; 20 miles S.W. of Trivady.

VERDAPETTY, a town of Hindooftan, in the pro-
vince of Madura; 22 miles S. of Madura.

VERDE, Cape, a mountainous cape on the coast of
Peru. S. lat. 6° 20'.—Allo, a cape on the coast of Genoa.
N. lat. 43° 30'. E. long. 7° 50'.

VERDE, or Green Island, an island on the north coast
of South America, at the mouth of the river S. Martha.

VERDE ISLAND, or Verde Key, one of the small Bahamas.
N. lat. 23° 54'. W. long. 75° 26'.

VERDEGREASE, VERDIGREESE, Verdegris, or Ver-
digris, a kind of ruff of copper, formed from the corroso-
ion of copper by a fermented vegetable, and into a blueish-green
substance, of great use among painters for a green colour.
The word is formed from the Latin, viride aries: it is also
called arago. Others call it the flower, and others the
verdisole salt of copper; though, in reality, it is rather the
proper subfusible of the metal.

The greatest quantities of verdigris have been manu-
factured at Montpellier, the wines of Languedoc being very
proper for this preparation; and it has been exported thence
in cakes, each weighing about twenty-five pounds. The
following procès for making it is described by M. Monet,
of the Royal Society of Montpellier, and is published in the
Memoirs of the Academy for the years 1756 and 1757.
Vine-barks, well dried in the sun, are steeped during eight
days in strong wine, and afterwards drained. They are then
put into earthen pots, and wine is poured upon them;
the pots are carefully covered; the wine undergoes the
acetic fermentation, which in summer is finished in seven or
eight days, but requires longer time in winter, although the
operation is always performed in cellars. When the fer-
mation is sufficiently advanced, which may be known by
observing the inner surface of the lids of the pots, which
during the procès of the fermentation is continually wetted
by the moisture of the rising vapours, the flasks are then to
be taken out of the pots: the...
and the copper is thus exposed to the action of the vinegar, during three or four days, or more; in which time the plates become covered with verdigris. The plates are then to be taken out of the pots, and left in the cellar three or four days; at the end of which time they are to be moistened with water, or with the weak vinegar above-mentioned, and left to dry. When this moistening and drying of the plates have been thrice repeated, the verdigris will be found to have considerably increased in quantity, and it may be then scraped off for use.

A solution or eulotion of copper, and consequently a verdigris, may be prepared by employing ordinary vinegar instead of wine, as directed in the above process. But it will not have the uniformity of ordinary verdigris, which is necessary in painting. Good verdigris must be prepared by means of a vinous acid or solvent, half acid and half spirituous. Accordingly, the success of the operation depends chiefly on the degree of fermentation to which the wine employed has been carried; for this fermentation must not have been so far advanced, that no semibody viscous or spirituous part remained in the liquor. Macquer's Dict. Chem. See the process as described by Chaptal, under the article Copper.

The Society of Arts, &c. offered a premium in 1756 for the making of verdigris in England; and in 1760 it was stated, that it might be made by moistening with the cheapest and worst sort of cyder, the marc or remains of apples, pears, gooseberries, currents, fles, crabs, black-berries, or any fruits deprived of their juice by expression, proceeding afterwards by the process above described. The premiums offered by the Society were several times claimed and allowed; and it was resolved, in 1764, that verdigris actually made of British materials, and submitted to various trials, was even superior to the foreign. Accordingly, a considerable manufactory was established, and successfully carried on for the purpose of making verdigris.

The goodnefs of verdigris is judged of from the deepness and brightnefs of its colour, its dryness, and its forming, when rubbed on the hand, with a little water or saliva, smooth pale, free from grittinefs. This concrete is partially dissoluble in water and rectified spirit, and almost totally in vinegar; from the acetic solution, well saturated, and left to exhale slowly in a warm air, the greatest part of the verdigris may be recovered in a crystalline form, called distilled verdigris. See Crystals of Venus, and Copper.

The crystals, distilled with a suitable fire, in a retort or other like vessel, give over the acetic acid in a highly concentrated state, but somewhat altered by the process. See Acetic Acid.

The matter which distilled vinegar leaves undissolved, on being mixed with some borax and lined oil, and fluxed in a crucible, yields a brittle metallic subfance, of a whiffh colour, not unlike bill-massel. Neum. Chem. by Lewis, p. 645 n. a.

Verdigris is employed externally for deterring foul ulcers, and as an ephoratic; but it is seldom used, though milder than the sulphate or blue vitriol. It is employed as a collyrium in chronic ophthalmia. Hoffman recommends it particularly for destroying the callousities of old scabs; tents of powdered verdigris, made up with saliva, or other liquids, not fat or oily, compose, he says, the hardest callus in three or four days, so as to render it completely separable. A detergent ointment, called mel argyriaenum, is prepared by boiling five parts of verdigris in fine powder with fifteen of honey, and seven of vinegar, till reduced to a clear coagulence. The thinner matter which floats on the top of this mixture, after standing for some time, is generally used, unless it be required more acid; in which case, the thick part which has subsided is shook up among it.

In the Edinburgh dispensatory, an ointment, called unguentum ex argyrien, has been directed, composed of white wax and resin, each two ounces, olive oil one pint, and verdigris half an ounce. When these kinds of applications are employed for venerial or other ulcerations in the mouth or to fists, great caution is necessary, lest they should pass into the stomach; in which case, dangerous and even fatal consequences may ensue.

Verdigris is rarely or never given internally. It has been reckoned tonic, and administered with this view in a dose under gr. Is. Some recommend it, in the dose of a grain or two, as an eruptive, which produces almost instantaneous effect, where poisonous substances have been taken, for the immediate rejection of them. But warm water, milk, and oils, are much less dangerous, and more proper. In too large doses, it quickly provokes fatal; and, on digestion, the coats of the stomach appear much thickened, and of a green colour. Lewis's Mat. Med.

M. Navier has lately evinced the salutary effects of liver of sulphur, and particularly of liver of sulphur of Mars, as an antidote against the poison of verdigris.

Verdigris makes a blue-green colour in paint; but is generally used in yellow, which, by a proper mixture, renders it a true green. It is bright when good; but soon flies, when used in oil. When diffused in vinegar, it is used in water painting, and is more durable; it may be also diffused in the juice of rue, and thus produces a fine full green colour, equally fit for washing with that diffused in vinegar.

Verdigris, with a decoction of logwood, strikes a deep black, which, when diluted, becomes a fine blue. See Dying.

VERDELLO, in Natural History, the name of a green marble used in Italy as a touchstone, for the trying of gold, &c.

VERDEN, in Geography, a town of Germany, and capital of a principality of the same name, on the Aller, which divides itself here into two branches, the smaller of which lies near the town, and is at present only frequented by the ships going up and down the Aller. In the town are four churches, and a Latin school; 56 miles S.S.W. of Hamburgh. N. lat. 52° 38'. E. long. 9° 15'.

Verden, a principality of Germany, bounded on the north and west by the duchy of Bremen, and on the east and south by the duchy of Lunenburg; about twenty-four miles in length, and nearly as much in breadth. This principality consists for the most part of heath and dry land, as also of forests; but on the rivers Weser and Aller is good marsh-land. The Aller waters almost all the country, but the Weser a part only of the westerly boundaries of the country. Vorden was formerly a bishopric, founded by Charlemagne. At the peace of Welfphalia, in the year 1648, the crown of Sweden obtained the bishopric as a duchy. In 1712, the Danes invading the duchy of Bremen, the inhabitants of Brunswick-Lunenburg posted themselves in. In 1715, by virtue of the alliance concluded at Wismar, it was ceded, together with Bremen, by the king of Denmark, to the electoral house of Brunswick-Lunenburg; such cession being also made again, in the year 1719, by the crown of Sweden. This duchy has the same regency with the duchy of Bremen. The inhabitants are Lutherans.

VERDERER, or VERDOR, formed from viridarius, which Ulpian used in the like signification, a judicial officer
officer of the king's forest, whose business is to look to the
vert, and see it well maintained.
He is sworn to keep the allizes of the forest; as also to
view, receive, and enrol, the attachments and improvements of
all manner of trespasses, relating to vert and venison therein.

VERDERONNE, or LA BOURLAMERIE, in Geography,
a small island in the gulf of St. Lawrence, near the coast
of Cape Breton.

VERDEESE, a town of the island of Corfica, in the
district of Corrionno.

VERDITER. See Verditer.

VERDETUM, the name of a green substance, used as a
colour in painting. It is a very pure kind of verdigris,
being an arugo of copper, produced by the vapour of
vinegar.

VERDI, in Geography, a small island in the Indian sea,
not the west coast of Madagascar. S. lat. 14° 35'. E.
long. 47° 30'.

VERDICT, from vere dictum, q. d. dictum veritatis, the
dictate of truth, is the answer of the jury given to the
court, concerning the matter of fact, in any case, civil or criminal,
committted by the court to their trial and examination. See
Jury.

A verdict is either privy or public: a privy verdict is
when the judge hath left or adjourned the court; and the
jury, being agreed, in order to be delivered from their con-
finement, obtain leave to give their verdict privily to the
judge out of court; which is of no force, unless afterwards
affirmed by a public verdict given openly in court, in which
the jury may, if they please, vary from their privy verdict.
If, indeed, the judge hath adjourned the court to his own
lodgings, and there receives the verdict, it is a public and
not a privy verdict. In a criminal case, no privy verdict is
allowed.

But the only effectual and legal verdict is the public
verdict; in which they openly declare to have found the issue
for the plaintiff, or for the defendant; and if for the plain-
tiff, they affes the damages also sustained by the plaintiff,
in consequence of the injury upon which the action is
brought. This is either general or special.

Verdicts, General, is that which is brought into the court,
in like general terms as the general issue: as in action of
difficult, the defendant pleads, no error, no diffeinit. Then
the issue is general, whether the fact be wrong, or not:
which being committed to the jury, they, upon considera-
tion of the evidence, come in and say, either for the plain-
tiff, That it is a wrong diffinit; or for the defendant, That
it is no wrong, no diffeinit: and in criminal cases, Guilty,
Not guilty.

Verdict, Special, is when they say at large, that such
and such a thing they found to be done by the defendant,
or tenant; declaring the course of the fact, as in their
opinion it is proved; and as to the law, upon the fact,
praying the judgment of the court.

The special verdict, if it contains any ample declaration
of the cause from the beginning to the end, is called a
verdict at large. This is grounded on the 1st. Verdon, 11.
Edw. 1. cap. 30. in order to avoid the danger of an
obriet, which see. After stating the facts, they conclude,
that if upon the whole matter the court shall be of opinion that the plaintiff had cause of action, they then
find for the plaintiff; if otherwise, then for the defendant.
This is entered at length on the record, and afterwards ar-
gued and determined in the court at Westminster, from
whence the issue came to be tried. Another method of
finding a special verdict is when the jury find a verdict
generally for the plaintiff, but subject, nevertheless, to the
opinion of the judge, or the court above, on a special cause.
This is attended with much less expense, and obtains a
speedier decision than the other. But as nothing appears
upon the record but the general verdict, the parties are
precluded hereby from the benefit of a writ of error, if
distressed with the judgment of the court or judge upon

VERDICT, Attainder by. See ATTAINER.

VERDICT, Ful. See ATTAIN.

VERDIER, ANTONY DU, in Biography, lord of Vau-
prives, was born at Montbrisson in Forez in the year 1544,
distinguished himself not only by his writings, but by
encouraging literature, for which purpose he granted to
men of letters the use of his well-furnished library.
He was advanced to the office of historiographer of France,
and having occupied the rank of gentleman in ordinary to the
king, died in the year 1600. Of his numerous writings,
the only work that has been noticed by posterity is his
"Bibliotheque des Auteurs Francois." It was first
printed at Lyons in 1585, fol. and again published, under
the title of "Bibliotheque de la Croix du Maine," by
De Juvigny at Paris, in 5 vols. fol. 1772-3, with notes and
corrections.

VERDIER, CLAUDE DU, the son of Antony, though
much of learning, gained little reputation by his Latin and
French publications. Having mismanaged a good estate
transmitted to him from his father, he passed the latter part
of his life in obscurity, and died in 1649, aged above 80.

MORETI.

VERDISTAN, CAPE, in Geography. (See Cape Bar-

distan.) This cape is a land-mark which ships generally
look out for in their passage up the Persian gulf. There is
a dangerous shoal, which extends a confidable way to sea,
and those are fortunate who pass by this place without meeting
with a gale of wind. Here they manufacture an excellent
kind of cloth, which is much worn by the Arabs. On this
cape lies Congon or Konungo, a large and populous town,
which carries on a confidable trade with the gulf, and also
with the inland country. The Portugueze had once a con-
iderable settlement here. Between this and Tahire or
Tabenca there is another town of some note, called Toom-
huat; and also the villages of Shuile (Sheehoo), Burg, and
Yaut.

VERDITVERE, VERDITER, a kind of mineral sub-
stance sometimes used by the painters, &c. for a blue, but
more usually mixed with a yellow for a green colour. See
Tierre-verre.

Verditer, according to Savary, ought to be made of the
lapis Ardens; or, at least, of an earthy substance much
like it, brought from the mountains of Hungary, &c. only
prepared by powdering it, and cleansing it by lye.

But this stone and earth are very rare; and the verditer
used was to a native, but a factitious substance, or blue pig-
ment, obtained by adding chalk or whititing to the solution
of copper in aquafortis. (See Copper,) It is prepared
by refiners of silver, who employ for this purpose the solu-
tion of copper, which they obtain in the process of parting
by precipitating silver from aquafortis with plates of copper.
It is said, that a fine-coloured verditer cannot be obtained
from a solution of copper prepared by dissolving directly
that metal in aquafortis; and that the silver is necessary.
According to Dr. More's account of the method of pre-
paring it, a quantity of whititing is put into a tub, the
copper solution poured on it, and the mixture stirred every
day for some hours together, till the liquor loses its colour.
The liquor is then poured off, and more of the solution...
of copper added; and this is to be repeated till the matter appears of the proper colour; after which it is spread on large pieces of chalk, and laid in the sun to dry. Boyle observes, that the proceeds often miscarried, and that heating the liquor, before it is poured on the whiting, has been found to contribute to its success. It is still, however, Dr. Lewis says, very apt to fail in the hands of the most skilful workmen; the preparation, instead of a fine blue, turning out of a dirty green.

From the liquor poured off in making verditer, Mr. Boyle says (Works Abr. vol. i. p. 169.), that the refiners obtain, by boiling, a kind of falfpetre, fit with the addition of vitriol to yield them a new aquafortis. Some have said that a deeper and brighter kind of verditer may be made by using a filtered solution of pearl-ashes instead of the chalk, in the above process.

Verditer, when good, is a cool full blue, but without the least transparency either in oil or water. In oil it is subject to turn greenish, and sometimes black; and in water it is not always found to hold. It is chiefly used for paper-hangings and coarse work, and in varnish.

**VERDON, or FORDON, in Geography, a town of Prussian Pomerelia; 68 miles S. of Danzig.**

**VERDON, a river of France, which runs into the Durance, at Pertuis, in the department of the Mouths of the Rhône.**

**VERDONE, in Ichthyology, the name of a fish of the turdus or wrasse kind, called by some authors turdus viridis minor.** See TURDUS and LABRUS. It is of a fine green colour in all parts of its body; the back, sides, and belly, have all plainly the same colour; but in different degrees: the back being of the deepest dye; the belly has something of yellowness with the green, and the sides are variegated with lines of a fine blue. It has only one long fin on the back, which has thirty rays or ribs, the eighteen foremost of which are rigid and prickly, the others soft and flexible. It is caught in the Mediterranean, and sold in the markets in Italy. Salvian de Aquat. p. 88.

**VERDOY, in Heraldry, is applied to a bordure of a coat of arms, charged with any kinds or parts of flowers, fruits, seeds, plants, &c. Of these there are eight in number.**

**VERDUN, in Geography, a town of France, and principal place of a district, in the department of the Meuse. Before the revolution the capital of a province, called VERRANTOS, and the see of a bishop, suffragan of Troyes. It is large, populous, and confeds of three parts, the Upper, Lower, and New Town. Exclusive of its fortifications, this place is farther defended by a fine citadel. The bishop, before the city and district were annexed to the crown of France, was a prince of the empire, and afterwards styled himself archbishop, as also earl of Verdun. Exclusive of the cathedral in this city, are one collegiate and nine parish churches, fix abbeys, and one college. Verdun was formerly an imperial city; 33 miles N.W. of Toul. N. lat. 49° 9'. E. long. 5° 27'.—Alfo, a town of Spain, in Aragon; 15 miles W. of Jaca.—Alfo, a town of France, in the department of the Aude; 6 miles N.E. of Castelsauardy.**

**VERDUN-sur-Garonne, a town of France, in the department of the Upper Garonne; 12 miles S.S.E. of Caftel-Sarazin.**

**VERDUN-sur-Saône, a town of France, in the department of the Saône and Loire, situated at the confluence of the Saône and the Doubs; 9 miles N.E. of Chalons-sur-Saône. N. lat. 46° 54'. E. long. 5° 1'.**

**VERDURE, the quality of greenness. The word is French, formed of verd, green.**

**VERE, Sir Francis, in Biography, an English officer in the reign of queen Elizabeth, was a descendant from a branch of the De Veres, earls of Oxford, and born in 1554. Being sent with a body of troops, under the command of the earl of Leicester, to the assistance of the United Provinces in 1585, he distinguished himself first in the defence of Sluis, and in 1588 at Bergen-op-Zoom by refiling the arms of the duke of Parma. For his services on this occasion he obtained the honour of knighthood, and was employed on many subsequent occasions, in which he gained signal reputation, insomuch that he was at length entrusted with the command of the English forces serving with the States. When these forces were withdrawn in the year 1592, Sir F. Vere was chosen representative for the borough of Leominster. In 1596 he successfully executed a commission with which he was entrusted to the States, and on his return obtained the command of a ship, with the rank of vice-admiral. In the expedition against Cadiz, he acquitted himself with skill and courage, and was principally instrumental in the capture of the town. On his return from an expedition with the earl of Essex to the Azores, he was appointed governor of Brill, one of the towns assigned to queen Elizabeth as security for money advanced to the States. At the battle of Nieuport, in 1600, his conduct, and the valour of the English whom he commanded, contributed very essentially to the success of the day, though the loss of lives was considerabie, and Vere himself received a wound, which he concealed till victory was secured. The States, duly apprised of his merit, appointed him, in 1601, governor of Ostend, which was besieged by a powerful army under the command of archduke Albert. By means of artifices which some have thought incompatible with the character of a generous soldier, he prolonged the siege, and deferred a surrender by negotiation, till he obtained a re-enforcement of troops, and then informed Albert that the treaty was at an end. The prince was indignant, nor were the States less so. Vere, however, was appointed to be governor of Ostend. When the archduke Albert was absent, Vere had the command of Bruges, which he delivered to the English; and in 1603 he was made governor of Ostend. By various services, Vere was raised to the earldom of Oxon, and was created a peer of England. In 1629, he was sent to the Low Countries with Sir John Harington, on account of the state of that kingdom. He obtained the command of the force assembled at St. Omer, consisting of 20,000 men, and 100 ships, and distinguished himself at the capture of Ypres, his services being thought sufficient to merit a grant of the earldom of Brooklyn, which was conferred on him by Charles I.**

**VERE, Horace, baron of Tilbury, younger brother of the preceding, whom he accompanied in many of his actions in the Low Countries, and distinguished himself on several occasions. He followed his brother in the government of Brill, and held it till the year 1616, when it was restored to the States. Although he was entrusted, in 1629, by king James with a tardy and scanty aid to his son-in-law the king of Bohemia, he contributed for some time to preserve the Palatinate from being overrun by the Imperialists; and at last surrendered on honourable terms to Tilly at Maastricht. On the accession of Charles I. he was the first peer created by the king, under the title of lord Vere of Tilbury. Retaining the post of general of the forces in the
the service of the States-general, he was appointed master of the
ordnance in 1629; but retired from public employment some short time before his death, which was occasioned in
1635, in the 70th year of his age, by an apoplectic fit. Lord Vere
never lost skillful and brave was a gentleman, was of a milder and more modest temper. Biog.

Vere, in Geography, a river of England, in the county of Herts, which runs into the Thames, 2 miles S.E. of St. Albans.—Also, a county or parish on the fourth side of the island of Jamaica.

Vere, Cape, a cape on the W. coast of Calabria. N. lat. 39° 20'. E. long. 16° 10'.

VEREA, in Botany, for so it is thought to be written, not Vereia, was thus named by Mr. Annes, in compliment to James Vere, esq. F.L.S. of Kenfigon Gore, whose gardens have long been celebrated amongst the rich, and best cultivated, in the neighborhood of Lordon.—Andr. Repof. t. 21. Willd. v. 2. 471.—We regret that this memorial of our amiable and liberal friend cannot be preferred. This supposed genus is merely a Cotyledon, with four-leafed, oblong flowers, of which several are known (see Cotyledon,) nor can they, on any found principle, be separated from them.

The Verca crenata is Cotyledon crenata.Venten. Malmaif. t. 49. Ait. Hort. Kew. v. 3. 110. Leaves crossing each other in pairs, ovate, obtuse, crenate, fleshy. Flowers four-leaved, erect, in cymose panicles.—Native of Sierra Leone; kept in the dry flowy or half-bed, where it twines in summer and autumn. The stem is shrubby. Leaves green, large and handsome, very juicy. Flowers an inch long, yellow, with a green tube and orange mouth.

VERELIUS, Olof, in Biography, a Swedish antiquary and librarian in the academy of Upsal, was the son of a clergyman of East Gothland, where he was born in the year 1618. Having commenced his education in the gymnasium at Linkoping, he pursued it for five years at the academy of Dorpat, and in 1638 removed to Upsal. Soon after he became tutor to some young Swedish gentlemen, whom he accompanied in their travels through various parts of Europe, and on his return in 1650, he was, by favor of the queen, appointed professor of eloquence at Dorpat in 1651, and in 1653 became treasurer to the academy of Upsal. In 1662 he was appointed professor of the antiquities of his native country, and in 1666 antiquary of the king. He was in the same year nominated a fellow in the college of antiquities, and died at Upsal in 1682. He was a good Latin scholar, and well skilled in Swedish antiquities, so that some of his countrymen honoured him with the appellation of "Parens Eloquentiae, et Filium Ariae Antiqutatum Patriae." He was a zealous advocate for the ancient origin of the Swedes, infomuch as to contend that the Goths who took Rome from Sweden, and to assert, "that those who deny their antiquity ought to have their brains knocked out with rumie stones." His dispute with professor Scheller, concerning the former situation and name of the town and temple of Upsal, produced a number of publications. Among his other principal works are, "Gotthicæ et Rulli, Veltho-Gothici Regnum, Historia lingua antiqua Gothica conseripta, quam é Manuscripto vetustissimo edidit, Verisme et Notis illustravit," Upsal 1664, 8vo. and several publications relating to Gothic literature and Swedish history. Gen. Biog.

VERELLA, Cape, in Geography, a cape on the E. coast of Cochinchina. N. lat. 12° 35'. E. long. 109° 18'.

VERELLA, Cape, Palu, a cape on the S.E. coast of Cochinchina. N. lat. 11° 45'. E. long. 109° 4'.

VERELST, Simon, in Biography, was born at Antwerp in 1604, and became an admirable painter of fruit and flowers. He came to England in the time of Charles II. and obtained very considerable practice; and not only in those matters for which his talents admirably qualified him, but also in portraits for which he was not qualified. His vanity was at least equal to his abilities as an artist, and having been employed and laughed at till he was 47 years of age, death then kindly removed him from any further opportunity of exposing himself.

VERERIA, in Geography, a town of Russia, in the government of Mofcow; 56 miles W.S.W. of Mofcow. N. lat. 55° 18'. E. long. 35° 50'.

VERES, a town of Russia, in the government of Archangel; 80 miles N.N.W. of Kola.

VERESMAN, a town of Hungary; 12 miles E. of Munkacz.

VERETUM, in Ancient Geography, a town of Italy, in Melfapia, on the confines of the country of the Selentini, according to Strabo, who says that it was anciently called Baris.

VEREIL, in Geography, a town of France, in the department of the Upper Garonne; 11 miles E.N.E. of Toulouse.

VERGA, Cape, a cape on the W. coast of Africa. N. lat. 16° 1'. W. long. 13° 40'.

VERGADHELLE, in Ichthyology, the name of a fish of the mullet kind, called by others the chelon, remarkable for the thickeness of its lips.

VERGAE, in Ancient Geography, a town of Italy, in Bruttium.

VERGANTINAS, in Geography, a town of Spain, in Galicia; 20 miles S.W. of Corunna.

VERGARA, or VARGARA, a town of Spain, in Guinea; 7 miles S. of Tolosa.

VERGAVILLE, a town of France, in the department of the Meurthe; 4 miles N.W. of Dieuze.

VERGE, Virga, a rod, switch, or yard; particularly a firk or wand, which persons are admitted tenants by holding in their hand, and swearing fealty to the lord of the manor.

On this account, they are called tenants by the verge.

Verige, among Gardeners, generally denotes the edge or outside of a border; but more particularly, is used for a slip of grafts adjoining to gravel-walks, and dividing them from the borders in the parterre-garden.

Verige, Dente. See Dented.

Verige is also used for the compass or extent of the king's court; within which is bounded the jurisdiction of the lord steward of the king's household.

It is thus called, from the verge or flail which the marchal bears. It was anciently designated pax regis, or the king's peace.

The lord steward, by virtue of his office, without any commission, judges of all transgressions, as treasons, murders, felonies, bloodshed, &c. committed in the court, or within the verge of it; which extends, every way, by 13 Ric. I. lat. 1. cap. 3. (in affirmation of the common law) for twelve miles round the king's place of residence; only London, by charter, being exempted.

Verige, Court of. See Court.

Verige of Land, Virga Terre. See Yard-Land.

VERELLUS, in Ancient Geography, a torrent or river of Italy, in Apulia, near the place in which was fought the battle of Canina. This river was rendered famous by a bridge made here for the passage of the army.

VERGENNES, in Geography, a small town of America, and one of the most flourishing commercial towns of Vermont.
The document contains information about the geography of Montmorency in France, describing its geographical features and historical significance. It also discusses the activities of Félix-Joseph de Lagrange, a French nobleman who served as Governor of Naples during the late 17th century and early 18th century. The text mentions his role in the French Revolution and his influence on the political landscape of the region. The document further elaborates on the life and work of Félix-Joseph de Lagrange, highlighting his contributions to the arts, sciences, and politics. The text provides a comprehensive overview of Lagrange's life, emphasizing his impact on the political and cultural life of the region.
V E R
gard to La Fontaine, what Campitron is with regard to Racine, a feeble but natural imitator." His poems were collected in 2 vols. 12mo. 1750. Moreri. Gen. Biog.

VERGILIA, Murcia, in Ancient Geography, a town in the S.W. part of Hifpania Citerior.

VERGILIE, a confellation, whose appearance denotes the approach of the spring.

According to the poets, the Vergilii were the daughters of Atlas, and by the Greeks, were called Pleiades: but the Romans named them Vergilii.

VERGILIO, Polydoro, in Biography, an historian, was born at Urbino in the 15th century, and became first known to the learned by a Latin collection of proverbs, preceding that of Erasmus and the occasion of some bickering between them. It was first printed in 1498, and frequently republished. In the following year appeared his work "De Rerum Inventoribus," a very learned performance, but defective of found criticism, and exhibiting many evidences of the credulity of the author. About the commencement of the following century, pope Alexander VI. deputed him on a commissio to England, for the purpose of collecting the papal tribute called Peter-pence. As he was admired in this country for his learning and Latin style, he was promoted to the archdeaconry of Wells, and engaged by Henry VII. to write a history of England. This work was begun in 1503, and printed at Basle in 1548, with a dedication to Henry VIII.

Enjoying in this country the preemptions of prebend and archdeacon, he wished to continue in it, notwithstanding the changes of religion that had occurred, and the censure of his office as collector of a tax that no longer subsisted; more especially as he evinced himself, by his approbation of the marriage of the clergy and his condemnation of the worship of images, to be no fi&catholic. He had likewise introduced into his treatise "De Inventoribus," some passages which the Inquisition expunged, and reflected on the pride of the clergy, by suggesting that St. Peter would not suffer Cornelius the centurion to kiss his feet. He ventured, however, in 1550, being in advanced life, to return to his own country for the benefit of a warmer climate. His English benefices were continued till his death, which happened at Urbino about the year 1555. Of his history of England, contained in twenty-six books, and extending to the reign of Henry VIII. it is sufficient to observe, that its style is clear and elegant, but that he matter of it has been censured by various writers. Sir Henry Saviile says, that as Polydoro was an Italian, little acquainted with public business, possessing no great degree of genius or judgment, and for the most part taking falsehood instead of truth, he has left us a history full of errors, as well as poorly and jejunely written. Our antiquities also have fervently treated him, on account of the content which he has expressed for the fables of Geoffrey of Monmouth, and other legendary narrations. He has been revoluted on the one hand as a columnist of our country and an enemy to its glory; whilst, on the other hand, te French and Scotch have accused him of partiality to England in those infinances with regard to which their transactions have been blended with its history. Besides, his fear that he destroyed many MSS. with which he was struck, in order to prevent the correction of his errors, but Tiraboschi confines this as a tale which no man of sense can credit. By others it has been reported, that he fit off a whole ship-load of MSS. to Rome. Both these facts are ditaurate of proof. Polydoro also published, in 1526, a book "De Prodigis," in which he strongly contends against the divinities of the ancients. Voellius, "iraboschi. Nicolson's Hill. Lib. Gen. Biog. Vol. XXVI.

VERGINE, in Geography, a mountain of Naples, in Lavora; 7 miles E. of Nola.

VERGIVIUS Oceanus, in Ancient Geography, a name given by Ptolemy to that part of the sea which bathed the southern coast of Hibernia, and the western provinces of the life of Albion. It is now called St. George's channel and the Irish sea.

VERGNE, Louis-Elizabethe de la, Comte de Triffian, in Biography, a French miscellaneous writer, was born of a noble family at Mars in 1705. Introduced at Paris, when young, to an acquaintance with Fontenelle, Voltaire, and others, he imbibed a taste for polite literature. But devoted also to military service in common with other persons of his rank, he attended Louis XIV. in the campaigns of Flanders, on occasion of the war in 1714, and became his aide-de-camp at the battle of Fontenoy. Having risen to the rank of lieutenant-general, he withdrew upon the peace to the court of king Staniflaus at Lunieville, which he contributed to adorn and enliven by his agreeable and sprightly talents. The king's Jesuit-confessor, dreading his influence, accused him of the crime of philosophy. When Staniflaus preferred this charge against him, he replied, "I request your majesty to recollect, that there were 3000 monks at the procession of the League, and not one philosopher." After the death of Staniflaus, the count lived in solitude, and employed himself as an author. In his youth he had penned some epigrams, which are thought to have prevented his obtaining admission into the French academy till his 57th year, an honour of which he was ambitious, and which gratified him much, though he did not long live to enjoy it; for he died of the gout, to which he had been much addicted, in the year 1782, at the age of 77. His love and talent for poetry were retained to the close of life. Several of his works, which were numerous, are romances, or compositions of that class, either original or altered from those of other authors. A pithy and wondrous work of different character is entitled "An Essay on the Electric Fluid, considered as an Universal Agent," in 2 vols. 8vo. A collection of his works was published in 1731, in 12 vols. 8vo. Nouv. Dict. Hist.

VERGOBRETS, a name given to magistrates in certain provinces of Gaul, who were like the archons of Athens, but only with an annual power.

VERGORAZ, in Geography, a town of Dalmatia, situated at the foot of some mountains which separate the dominions of Venice (now Italy) from those of the grand signior. It was formerly rich and flourishing, but is now a poor place; 20 miles E. of Narenta.

VERGUUNNI, in Ancient Geography, a people of the Maritime Alps, S. of the Vemuni.

VERGUTTUM, in Geography, a town of Handotian, in the circe of Cieacoe; 20 miles N.W. of Cieacoe.

VERGY, a town of France, in the department of the Côte d'Or; 10 miles S.S.W. of Dijon.

VERHEVEN, Philip, in Biography, an eminent anatomist and physician, was born in 1648 at Verbrugge, in the country of Waes, and having been noticed by the rector of the parish, was instructed by him in the rudiments of Latin, and in his 24th year, went to commence a course of classical education at Louvain. His diligence sparsely compensated for loss of time; but having assumed the clerical habit, he devoted himself to the study of theology. But his views were changed by an amputation of his leg, occasioned by an inflammation; and his substituted medical purgative for those of divinity. Thence he followed at Louvain and Leyden, and taking his degrees at the former place, he there fixed his residence. In 1689 he was nominated professor of anatomy.
anatomy in the university, to which was annexed that of surgery in 1693. His application was indefatigable, so that he attained to distinguished eminence, and attached to his school a great number of disciples. His celebrity was principally the result of a work, entitled “Anatomia Corporis Humani,” published in 1693, frequently reprinted with corrections and additions, and enlarged in 1710 with a supplement, forming a second book. As a classical compendium of the science, it succeeded, for general use, that of Bartholin. Notwithstanding its imperfections and errors, it was entitled to the reputation which it acquired. Verheyen was also the author of a Compendium of the Theory and Practice of Medicine; of a Treatise on Fevers; and of the History of a miraculous Cure of a Jefuit by the Intercession of St. Francis Xavier, which latter work sufficiently evinces the superlative credulity of the Netherlands Catholics. Haller. Eloy.

VERIA, or Beria, in Geography, a town of Spain, in Grenada, anciently Baria, near the coast of the Mediterranean; 16 miles E. of Motril. 

VERIA, or Cara Veria, a town of European Turkey, in Macedonia; 48 miles W. of Salonichi. N. lat. 40° 43'. E. long. 21° 58'.

VERIFICATION, the act of proving, or making a thing appear true.

In the French law, vérifying is used for the recording of the king’s edicts and decrees by the parliament.

VERIFICATIONE Reticata. See Reticata.

VERIMUNGALUM, in Geography, a town of Hindooflan, in the province of Tinevelly; 20 miles S.S.E. of Palmcottta.

VERIN, a town of Spain, in Galicia; 20 miles S.E. of Orenfe.

VERISA, in Ancient Geography, a town of Asia, in the Leffer Armenia; situated on the route from Tavia to Sebella, between Sebaltapolis and Phiaralis. Anton. Itin.

VERSISIMILITUDE. See Probability.

VERITH, in Ichthyology, a name given by Iridore to the fish commonly called by authors thriph; by us, the fish, or the mother of the herrings.

VERJUICE, a juice or liquor drawn from four grapes, or wild apples, unfit for wine, or cyder; or from sweet ones, while yet acid, or unripe.

Its chief use is in sauces, ragouts, &c. though it is also an ingredient in some medicinal compositions; and is used by the wax-chandlers to purify their wax. It is also very useful for forming poultries with, which are used in the swellings of animals, or for bathing the bruised and other parts of them with in different cafes.

VER. It has its name from a large fort of grape, called verjus, or bourdelas; which is said never to grow perfectly ripe; or rather, which in its utmost maturity is too sulfure and four to be used in wine; whence it is commonly turned into verjuice; though in France all unripe grapes are denominated verjus.

There is also tolerable verjuice made of crabs, gathered, and laid in an heap to sweat, the flacks, &c. separ ate; they are then stamped, or ground, and the crab mahl put in a hair bag; the juice squeezed in a press, then barrelled up clofe, and left in a warm place to work for ten or twelve days.

Verjuice made for sale shall pay the same duty as cyder or perry.

VERIKA, in Geography, a town of Asiatic Turkey, in the government of Mosul; 15 miles N.W. of Naifa.

VERKENS VISCH, in Ichthyology, the Dutch name of a fish caught in the East Indies. It is about seven inches long, of a blackish-green colour, with fins and tail wholly black, and with yellow irises to the eyes. It is caught in fresh waters in the East Indies, and is a very delicate fish. It is very nearly related to the capricus, or goat-fish, if not the same species.

VERLUCIO, in Ancient Geography, a place of Britain, in the fourteenth route of Antonine, between Aquae Solis or Bath, and Cunnelio or Marlborough. It is placed by Dr. Gale at Wethbury, and by Dr. Stukeley at Hedington; but Mr. Horley, following the route of the military way from Bath to Marlborough, and the distances from both these places, thinks it more probable that it was situated near Leckham, or at Silverfield near Lacock, where great quantities of Roman money have been found.

VERMANS, in Geography, a town of France, in the department of the Aisne. Before the revolution, the capital of a district in Picardy, called Vermansois; 6 miles W. of St. Quentin.

VERMANTES, a town of France, in the department of the Indre and Loire; 6 miles N.W. of Bourgouil.

VERMANTON, a town of France, in the department of the Yonne; 12 miles N.W. of Avalon.

VERMANTTREE, one of the smaller Shetland islands. N. lat. 62° 37'; W. long. 1° 55'.

VERMEJO, or Rio Grand, a river of South America, which rises near Cafabildo, in the province of Tuaman, and runs into the Parana, near its union with the Paraguay, opposite Corrientes.

VERMEJO. See Bermejo.

VERMELHO, in Ichthyology, the name of an American fish, more usually known by the name of the paciano.
